At Silverton, Colorado, the motive power is also derived from a distant water course. Three miles away a special double-nozzle Peltou wheel, four feet in diameter, running at 225 revolutions per minute under a head of 180 feet, has been installed. This drives a 150 kilowatt 2300 volt General Electric three-phase generator. The greater part of the current is taken to a 125-horse power induction motor, which operates the mill, and which, wound for 2000 volts, is used without transformers. The balance of the current is utilized at the mines for the operation of arc and incandescent lamps, and the driving of smaller motors operating pumps, ventilators, etc., the pressure of the secondary current for these motors being reduced, by step-down transformers, down to 220 volts. This plant is a model three-phase transmissiou, and in its operation since its installation has proven both economical and fully satisfactory.

AT the last meeting of the Technical Society Mr. Medina, of the Postal Telegraph Co., delivered a very interesting address on the "Transmission of Intelligence by Electricity," among other things lucidly explaining the theory and workings of the quadruplex.

DELINQUENT SALE NOTICE.

DUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California; location of works, in the counties of Alameda and Santa Clara, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 7) levied on the 22d day of January, 1895, the several amounts set opposite the names of the respective shareholders, as follows:

Name	No. Certificate.	No. Shares.	Amt.
Charles L. Beuton	567	200	$25 00
Charles L. Benton	569	100	12 50
Mrs. Ellen Dwyer	124	100	12 50
Edward Fox	524	400	50 00
Mrs. Elma Glover	413	60	7 50

And in accordance with law, and an order of the Board of Directors, made on the 22d day of January, 1895, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, No. 214 Pine street, on THURSDAY, the 21st day of March, 1895, at the hour of 2 o'clock P. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

JABEZ HOWES, Secretary.

Office—214 Pine street, Room No. 5, San Francisco, California.

NOTICE OF POSTPONEMENT.

In accordance with an order of the Board of Directors of the Dumbarton Land and Improvement Company, adopted at a regular meeting, held on the 26th day of February, 1895, the day of sale for unpaid Assessment No. 7 is postponed to THURSDAY, March 28th, 1895, at 2 P. M.

JABEZ HOWES, Secretary.

Office—214 Pine street, Room 55, San Francisco, California.

DELINQUENT SALE NOTICE.

REED MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Ferguson Mining District, Helene, Lincoln county, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment No. 1, levied on the 31st day of December, 1894, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
J. H. Isham, Trustee	6	500	$10 00
J. H. Isham, Trustee	7	2,500	50 00
J. H. Isham, Trustee	8	50	1 00
J. H. Isham, Trustee	9	50	1 00
J. H. Isham, Trustee	14	33,400	668 00
J. H. Isham, Trustee	13	73,000	1,460 00
J. H. Isham, Trustee	18	75,000	1,500 00
Geo. G. Reed	15	12,857	257 14
Geo. G. Reed	17	2,143	42 86

And in accordance with law, and an order of the Board of Directors, made on the 31st day of December, 1894, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 33, Tenth Floor, Mills Building, San Francisco, California, on WEDNESDAY, the third (3d) day of April, 1895, at the hour of 11 o'clock A. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of the sale.

J. H. ISHAM, Secretary.

Office—Room 33, Tenth Floor, Mills Building, San Francisco, California.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

What a Man's Life is Worth.

Decisions in two damage suits against the Ann Arbor railway for the deaths of William Beaulien and George Alberts, employes of the road, were rendered at Toledo, Ohio, last week, by Judge Ricks. They are of unusual importance because of determining the maximum sum to be recovered in federal courts in cases of this kind. Judge Ricks said: "One of the most difficult questions for a court to determine is for a correct and just measure for damages in a case of this kind. It is hard to say that a human life is not worth such a sum as the master has given in this cause, because the records show these men were of excellent habits, fond and affectionate husbands and in every way a help and comfort to their families and useful to the public. In a large number of States where the limit for the loss of life has been fixed by the Legislature, the sum of $10,000 has been fixed as the maximum allowance to be made. This is a legislative construction of a fair maximum sum to be awarded in such case. I think the court may properly, therefore, accept this concordant judgment of so many different State Legislatures as justifying it in saying that the maximum ought not in any one of these cases to exceed that sum."

A new launch ("Satellite") is now in the Union Gas Engine Co.'s works being fitted with motive power. The motor is a twelve H. P. marine gas engine of new pattern, low and compact. The reverse gear is also a new design, and built expressly for the purpose. She will use a thirty-inch four-blade propeller, and is expected to attain a speed of ten or twelve knots in good water. The boat was designed and built in Seattle, and her model is said to be upon finer lines than any launch heretofore designed on the coast. The hull is of oak and cedar, staunchly built in every way. The dimensions are 35 feet 6 inches in length and 6 feet 8 inches beam, and she will draw, when loaded, about fourteen inches forward and three feet aft. Her cabin is twenty-three feet in length, divided into three compartments, all enclosed by large plate-glass panels. The interior of the cabin is handsomely finished in curled maple and ash, and is provided with every modern convenience that ingenuity can devise to assure the comfort of half a dozen passengers, including a fifty candle power searchlight and incandescent lamps fed from storage batteries concealed in lockers. The "Satellite," when complete, will cost about $2500. The owner—Dr. V. P. Buckley—will use her as a pleasure craft on the bay of San Francisco. She will be launched about the 1st of April.

The requisites of protective painting for structural iron work have been made the subject of careful investigation by Mr. Wallis, of the Association of Engineers, Virginia, and the results of his studies in this direction have now been published. He recommends, as essential, that the first coat be of red lead grouud in raw linseed oil, and used within two or three weeks after mixing, being also kept thoroughly mixed while in use, this coat drying in from twenty-four to thirty hours. If the finish is to be black the uext two coats should be made up from a paste composed of sixty-five per ceut of pigment and thirty-five per cent of raw oil, the pigment to consist of sixty-five per cent of sulphate of lime, thirty per cent of lampblack, and five per cent of red lead as a drier, the whole being thinned to a proper consistency with pure boiled oil. If the finish is to be of red or brown the paste should be composed of seventy-five per cent of pigment and twenty-five per ceut of pure raw oil, the pigment to consist of fifty-five per cent of sulphate of lime, forty per cent of oxide of iron, free from sulphur and caustic substances, aud five per cent of carbonate of lime as a drier, the sulphate of lime to be fully hydrated. The estimated cost of such paint, ready for use, is about sixty cents per gallon.

An English court has decided regarding property rights in photographic portraits, that the copyright belongs to the sitters when they order the portrait and pay for its being taken. The only claim for copyright by the photographer is when he invites sitters to have their likeness takeu, and when they assent to sit without payment, doing so for purposes of publicity or advertisement.

"There is no use of walking the floor with a felon," says a gentleman who has had some experience in that direction. "Wrap a cloth loosely around the felon, leaving the end open. Pour gunpowder in the end and shake it down until the felon is covered, then keep it wet with camphor. In two hours the pain will be relieved, and a perfect cure will be sure to follow."

Dr. Pashkiff, of Russia, advocates the dressing of recently received wounds with a thin layer of ashes prepared by incinerating some cotton stuff or linen. The blood mingles with the ashes and forms a protecting surface, uuder which the lesion heals rapidly.

San Francisco spent nearly $40,000,000 for imported merchandise in '94. One-third of that sum could be kept at home under improved and legitimate industrial conditions.

Greenwich records show that for fourteen years there has been an average of but twenty hours of sunshine in London in December.

DEWEY & CO., 220 Market St... SAN FRANCISCO,
PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, March 7, 1895.

There was no change of note during the week. Silver has settled down to a steady "60½" day after day. The suggestion made in this column a few weeks ago that the silver market should be here and not in London, has been copied approvingly in nearly every mining journal of any importance all over the country. On this subject the following regarding the manipulation of the silver market is of interest:

The bulk of the silver bullion business done in London passes through five brokerage firms. These are the houses of Samuel Montague & Co., Sharpe & Wilkins, Mocatta & Goldsmidt, Pixley & Abell and H. A. Hertz. The second, third and fourth-named firms absolutely and arbitrarily fix the daily price of silver. The first and fifth named firms could doubtless be members of the combination, but for reasons of their own prefer not to be bound by its rules. They accede ordinarily, however, to the price as fixed. Representatives of these three firms meet every day in the office of Sharpe & Wilkins, and, at 2 P. M., give out the price for the day to the waiting crowd. This is telegraphed at once to the exchanges of the world. The price, however, is really fixed by foreign banks which purchase silver, and with which these brokers have previously been in consultation.

Except for an abortive attempt by American producers a few years ago, no serious effort seems ever to have been made to resist this arbitratory rate. London purchases about about two-thirds of the entire silver product of the world, and of the remaining third America consumes the larger part. These five firms thus represent the purchasers of practically two-thirds of the product.

Until a few years ago the first four named firms did practically all the business, but the London clearing-house, through which the Rothschilds and other large firms operate, added silver to its transactions, and is now a large purchaser. Last year its transactions were 23,000,000 ounces. Its representative is H. A. Hertz. Inquiries made in several most influential quarters by a *World* representative would seem to indicate that, while the arbitrary action of these firms is much resented by the producers, the remedy is really in the hands of the mining companies, if they should combine against the solid combination of the chief buyers. It is stated by the brokers themselves that their only clients are these purchasers, and that the American producers do not employ them, and that therefore their sole interest is to fix the lowest price possible. Buyers are united, while sellers are supine and divided. Only Chile and the South American States send their silver product directly to London for sale by brokers acting in behalf of producers, and are therefore anxious to get the best price possible for their clients. Producers in the United States, on the contrary, keep their product at home until it is sold at the price fixed in London, with no effort apparently and no concerted action to make it to the interest of brokers here to get higher prices. It is the opinion of at least one of the firms above named that the price of silver would be materially enhanced, but of course only after a severe struggle, if American producers should, acting in concert, ship their silver here in advance of sale, as do the South American States, and make it to the interest of Loudon brokers to get the highest instead of, as now, the lowest price.

The San Francisco agents of China and Japan hankers are checking the flow of silver from Colorado, Utah and Nevada to the Orient by way of New York and are shipping bullion to Hongkong and Yokohama from this port. These silver shipments are increasing monthly.

The Selbys separate the gold and silver in the hullion, after which the silver is reshipped abroad in solid bars. The cost of shipping one thousand dollars in fine silver from Denver to Hongkong via New York and London is $18.06, and by way of San Francisco $14. The Bank of California and the French bank here have in a large measure changed the flow of the immense silver output, which is a commercial triumph for San Francisco.

China, Japan, India and other Oriental countries have for years been the largest consumers of silver in the world, having received through San Francisco and London during the past six years $342,000,000.

In the nine years ending December 31st, '94, the shipments from San Francisco to China and Japan amounted to $97,164,480 in silver bars, and 111,023,432 Mexican dollars.

For some months past the silver product of the many big properties in Utah and Colorado has been marketed here, for direct shipment to the silver-using countries of the Orient. The Ontario and Daly mines are among the Utah producers which have disposed of their output in this manner. The San Francisco market rules a few points higher than the New York quotations, and there is an advantage in the cost of transportation.

Owing to the relations existing between England and India it is not probable that silver consigned to India will be sent by way of San Francisco. London merchants and bankers have a monopoly of that business and will retain it as long as they can, as the English Government coins the silver sent to India into rupees and of course makes a large profit on the coinage.

Mining Share Market.

SAN FRANCISCO, March 7, 1895.

Favorable news was received from the Comstock during the week, and there was increased business at stronger prices.

Money paid for labor on and around the Comstock in February aggregated $68,501.66. The pay roll of the Con. Cal. and Va. mine was $9403, the Ophir $3389, Chollar $4948, Hale & Norcross $2168.50, Yellow Jacket $2727, Crown Point $4298, Belcher $3046 and Alta $2414.

Following is a statement of the cash balances of certain mining companies on the first Monday of March as required by law.

BODIE MINES.			
Bodie	$11,611	Con. New York	510
Bulwer	2,473	Crown Point	295
Mono	4,158	Exchequer	2,486
Syndicate	839	Gould & Curry	13,451
WASHOE MINES.		Hale & Norcross	19,243
Alpha	$6,143	Justice	160
Alta	10,612	Kentuck	3,671
Andes	5,494	Lady Wash'n	2,104
Belcher	2,453	Mexican	15,097
Best & Belcher	14,418	Ophir	8,078
Bullion	8,671	Overman	6,759
Caledonia	3,222	Occidental	466
Challenge	106	Potosi	20,460
Chollar	6,358	Savage	3,568
Con. Cal & Va	94,520	Sierra Nevada	20,915
Con. Imperial	841	Silver Hill	1,294
Confidence	7,225	Union Con	13,053
		Utah	2,162

The delinquent assessment sale of the Confidence took place yesterday. Less than 100 shares were sold for non-payment.

The following illustrates the changes of the week:

Mines.	28	7
Alpha	.....	$ 09
Alta Consolidated	$ 33	32
Andes	26	.....

Potosi	50	56
Savage	44	47
Sierra Nevada	61	71
Union	44	56
Utah	06	.....
Yellow Jacket	59	67

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CONCENTRATOR AND AMALGAMATOR.—Henri Baudouin and Joseph Southern, Grass Valley, Cal. No. 534,777. Dated Feb. 26, 1895. This invention relates to an apparatus for working the ores of precious metals. It consists of a band journaled upon a vertical shaft and having a crank or cam connection by which it is caused to oscillate backward and forward around this shaft. The pan has an inclined bottom with annular overflow channels to contain quicksilver, and a correspondingly channeled disk supported above the bottom, having its inner side inclined with relation to the bottom in a horizontal plane. A central receiver around the top of the shaft serves to receive the pulp, and from holes around the bottom of the receiver this pulp is distributed outwardly over plates or screens, falling thence through upon the inclined and channelled disk where it encounters the quicksilver upon the surface of the disk and passes thence to the corresponding quicksilver channels in the bottom of the pan. Above the plate are copper and zinc hoops suitably arranged to produce an electrical action when they dip into the current of passing pulp. The hoops and battery elements are properly supported by arms above the plates and bottom. A suitable discharge is arranged for the waste pulp, either at the periphery or center of the pan, according to the angle at which the bottom is formed.

ROD COUPLING.—Ellery M. Hoagland, Salinas, Cal. No. 534,507. Dated Feb. 19, 1895. The object of this invention is to provide a coupling for rods, which can be quickly made and broken, and while coupled will remain absolutely secure, thereby especially adapting the device for the joining of all rods, and particularly the rods used in well boring. In well boring it is required that the tool below be often withdrawn to discharge and to clear it. This, after it has gone down a considerable depth, is a matter of time, as it is necessary to uncouple the section of the rod as the device is hauled up, and as it is put down again to couple the sections together once more. It is therefore of the greatest importance that the coupling and uncoupling be done with great facility and rapidity; but at the same time the coupling should be an accurate and positive one, precluding all danger of becoming accidentally uncoupled, and one which will permit both the churning action and the rotary movement without lost motion or without yielding or giving in the slightest. These results are all reached by this coupling, which consists of a sectiou having a shank reduced in thickness and provided with a notch in one of its edges, a second section having a hollowed or recessed body portion opeu at both sides with a directing wall closing a portion of the opening at one side and a stop wall closing a portion of the opening at the opposite side, and disposed in a plane below that of the directiug wall, said stop wall adapted to engage the notched portiou of the first named section.

FAIRFAX VILLA COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Fairfax, Marin county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of February, 1895, an assessment, No. 2, of one hundred dollars ($100) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 56, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of March, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 16th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. STADTFELD, JR., Secretary.

Office—Room No. 56, No 309 Montgomery street, San Francisco, California.

CHALLENGE CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Gold Hill, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth (19th) day of February, 1895, an assessment (No. 18) of Five Cents (5c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 38, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the twenty-sixth (26th) day of March, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the sixteenth (16th) day of April, 1895, to pay the delinquent assessment, together with cost of advertising and expenses of sale.

By order of the Board of Directors.

C. L. McCOY, Secretary.

Office—Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Auburn, Placer county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the eighteenth day of February, 1895, an assessment (No. 5) of Two (2c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, Room No. 28, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on WEDNESDAY, the seventeenth day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. R. SPINNEY, Secretary.

Office—No. 310 Pine street, Room No. 28, San Francisco, California.

IOWA MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia City, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 6th day of March, 1895, an assessment, (No. 20) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 2, 419 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 9th day of April, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 27th day of April, 1895, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. L. THOMAS, Secretary.

Office—Room 2, 419 California Street, San Francisco, California.

Coast Industrial Notes.

The Standard Con. Mining Co. is having a Dow pump built for the main shaft.

The Los Angeles Consolidated Electric Railway Company bondholders will take control, improve the plant, and place the road upon a paying basis.

—The annual report of Charles Sleeper, manager of the San Francisco Clearing-house, gives the clearings in 1894 at $675,526,806, against $699,285,778 in 1893- a decrease of $10,758,972.

The Mexican government has pledged itself to admit free of duty all materials and machinery to be erected on the grounds of the international exposition to be held at the City of Mexico in 1896. Greatly reduced railroad rates are also promised.

—H. A. Robertson, of this city, one of the owners of the big pile raft that went to pieces some months ago while being towed here has commenced on another one near Astoria, Oregon, which, when completed, will cost $30,000. No attempt will be made to tow it to San Francisco until summer.

—The contract for the Hayward mill at Silver Bow Basin, Juneau, Alaska, has been given the Union Iron Works. It will be 30 stamps, and will cost in place, ready for work, about $51,000. The mill is to be delivered May 1st., and 30 days after the company will be able to begin crushing 100 tons a day.

The Union Iron Works is patiently awaiting the arrival from the East of the belt armor for the battle-ship Oregon. It was scheduled to reach here as far back as 1892. It was subsequently ordered in 1894, and is now expected to arrive any day. When the armor is placed in position the battle-ship will be completed.

W. B. Honeyman, of the Portland linseed oil works, has made contracts with Linn county farmers, in Oregon, for 2000 acres of flaxseed, for which he has contracted to pay $1.80 per hundred. This will bring to the growers something upward of $20,000. Mr. Honeyman furnishes the seed to sow the 2000 acres.

—The colossal figure of Progress, which will surmount the dome of the City Hall, has been modelled by Marion Wells, the sculptor, and will be soon cast. It is 22½ feet high, and represents a winged female holding aloft a torch. At night this torch will be brilliantly illuminated. It will be over 300 feet above the sea level.

—The New England Fish Company, whose headquarters are at Boston, and who have been fishing for halibut in British Columbia waters all winter, have closed the season's operations. The total catch for the season amounted to 900,000 pounds, and the price realized was about seven cents per fish. Twenty-five cars were shipped east.

A Co-operative Company has been organized to reopen the Renton coal mine, ten miles south of Seattle, Wash., which has been closed for the last eight years. It was last operated by Mr. Simpson of San Francisco, but when his miners struck he closed it and has never reopened it. The company, with $100,000 capital stock, will be composed of miners and consumers, none of whom will be allowed to vote more than ten shares, and expects to employ about 300 men.

The new west-bound freight tariff from Chicago and common points, and from Mississippi and Missouri River common points, went into effect last Tuesday. The new rates do not effect California consumers very materially save in the case of iron and iron commodities, which are raised from thirty cents to fifty cents, as the minimum rate. The rates do not apply to points in California south of Lathrop, Stockton or San Jose, on shipments routed via Portland, Or.

—A syndicate of well-to-do Italians have hit upon a novel plan to supply the San Francisco market with fresh halibut. They have purchased the once famous racing yacht Cyclone, and intend putting in a large well amidship capable of holding many thousands of gallons of water. In this way a whole cargo of fish, caught on the halibut banks, can be kept alive until delivered at the city markets. By this means they expect a much higher price for their product than do the fishermen who bring in their product dead.

James Treadwell, president of the San Francisco and San Joaquin Coal Company, says: "There are twenty million tons of coal in sight near Livermore. The location is eight miles southeast of Livermore, and the seam has been traced six and a half miles in length and a mile in width. This coal is so abundant, and is extracted so cheaply, that it can be mined and shipped to Oakland with a profit at $1.50 a ton." If so, this would revolutionize manufacturing methods of this city, where cheap fuel is the one great lack.

—The largest wooden drydock on the coast was launched yesterday, at Benicia, for the California Drydock Company, at the foot of Spear street, this city. Over 150 men worked on it for six months, and a million and a half feet of Oregon lumber, 100 tons of iron, 40 tons of copper and 29,000 pounds of yellow metal have been used in building it. Its length is 301 feet; depth of hold, 10 feet 9 inches. The pumping plant of eight pumps, is guaranteed to lift 2,250,000 gallons of water in two hours. The cost of the dock, which will accommodate a steamer 300 feet in length, is nearly $200,000.

Traffic relations with the Santa Fe, Prescott and Phoenix road have been opened by the Santa Fe, and it is anticipated that after the formal opening next Monday there will be considerable travel in that direction. The road runs from Ash Fork, on the Atlantic and Pacific division of the Santa Fe system, to Phoenix, the entire length of the line being 196 miles. Among other of the principal owners of the road are reported to be the following capitalists: N. K. Fairbanks, Chicago; Dexter M. Ferry, W. Bowen and S. Murphy, Detroit; C. Arms, Youngstown, O.; and W. Hadley, Los Vegas, N. M.

A new industry has been added to California's many sources of wealth. This is the cultivation of the yellow dock, botanically known as the canaigre, the root of which is used in tanning leather. This root contains thirty-two per cent of strong tannic acid. The wild dock grows all through the San Joaquin Valley, and with cultivation the root may be increased fourfold. As the supply of oak for tanning is running low, both here and abroad, the importance of this despised weed may be estimated. A company has been organized to plant five thousand acres of the dock in Merced, and a big tannery will be built.

—The battle-ship Olympia, built by the Union Iron Works, has been finally accepted by Secretary Herbert. The Naval Board of Examiners in their report take occasion to justly compliment the San Francisco builders, and say: "The board congratulates the department on the addition of the Olympia to the Navy of the United States, which, with its great fighting power, speed and elegant appearance, is a credit to the navy and American mechanical skill. It is with great pleasure that the board calls attention of the department to the excellent work done by the Union Iron Works, their care in all the details of construction and the clean and finished condition of the vessel."

—The work of constructing branch lines of the Mexican International railroad, from Monclova, Mexico, to Sierra Mojada, and from Reatea to Monterey, has been suspended, the order coming from C. P. Huntington not to construct the branches at the present time. It is said he and his associates have been trying to get control of or to purchase or lease the Monterey and Mexican and Gulf railroad, which is one of the most profitable railroad properties in Mexico, and it is hinted that the building of the proposed extensive joint lines of the Mexican International was an attempt to bluff the owners of the Monterey and Mexican and Gulf into making a deal. The proposed branches would be competing lines against the Gulf Coast.

—The new whaleback steamer City of Everett arrived here last Monday, sixty-two hours from Port Townsend. She brought down twenty-three passengers, among whom was Captain McDougall, the inventor. She carries 3800 tons of coal on a mean draft of 19 feet 6 inches. On the deck are four big tarrets, each containing two hoisting engines. The vessel has eight hatches, which open nearly the entire length of the ship. Her engines are triple expansion. The deck is protected by heavy wire cables stretched from iron stanchions at intervals of fifteen feet. The main house rests on two tarrets set on the after part of the deck, from which two gangways run forward to the bridge, on which is the captain's room, pilot and chart house. Steam steering-gear is used. The Everett will discharge at Port Costa and return to Comax, B. C., in ballast.

Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals Without Quicksilver. By GUIDO KUSTEL, M. E.

This race book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, $3, postpaid. For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages, octavo. Illustrated by twelve lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

GATES ROCK AND ORE BREAKER

OVER 3000 IN USE THROUGHOUT THE WORLD

PRODUCES A MORE PERFECT CUBIFORM MATERIAL AND A GREATER QUANTITY IN A GIVEN TIME PER HORSE POWER USED THAN ANY OTHER CRUSHER ON EARTH.

CAPACITIES UP TO 150 TONS PER HOUR. NINE DIFFERENT SIZES.

WATER WHEEL

CASCADE WATER WHEEL

Adapted to all heads, from 30 FEET TO 2000 FEET. Our experience of 33 YEARS in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.

JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will have inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S. F.

MINE BELL SIGNALS.

Adopted, Used and In Force in Accordance with State Law.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

MINING AND SCIENTIFIC PRESS.

AND PACIFIC ELECTRICAL REVIEW.

VOLUME LXX. Number 11. SAN FRANCISCO, SATURDAY, MARCH 16, 1895. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

De Beers Con. Mine Report.

From Gardner F. Williams, head manager, is received the sixth annual report of the De Beers consolidated mines, of Kimberly, South Africa. During the year the diamonds produced realized £2,820,172; the expenditure was £1,690,584, leaving a profit of £1,129,588—about $5,645,000 on a capital of $19,750,000. The magnitude of the scope of this great company is illustrated by their reserve fund of £726,000; their £300,000 investment in the British South Africa Co., and their large holdings in colonial railway and coal companies.

The average number employed in the De Beers-Kimberly mines during the year was 8113—1507 whites and 6606 blacks.

The "nationality of employes" table is interesting:

	In and About the Mines and Floors.	*At the Workshops.*
English...	52.2	41.5
Scotch	6.2	23.3
Irish...	4.8	2.4
Colonial..	33.1	27.1
European.....	1.8	4.2
Other nations..	1.9	1.5
Total.....	100	100

Accompanying the detailed financial report are elaborate plates illustrating the plan and workings of the mine and plant.

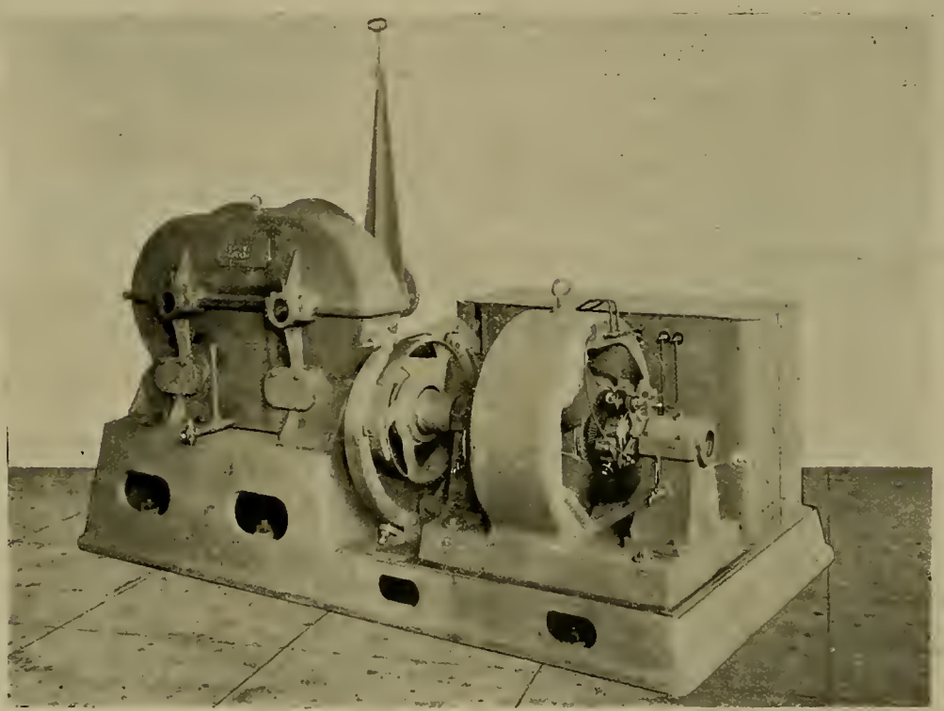
At the general meeting Cecil J. Rhodes presided. Among other things he said:

"Gentlemen, we made an effort in America to show our diamonds to the Americans during the great World's Fair at Chicago, and we spent £10,000 upon our exhibit. Brother Jonathan, with his usual cleverness, as soon as he had seen our diamonds and was gratified by our expenditure, attempted to put a prohibitive duty upon them. I do not blame Brother Jonathan, but one of the amusing things about it is that, having promoted a big show, and having invited the world to that show, as soon as it is over, he says: 'I don't want to see you again.' I do not know if we would be wise in retaliating. I believe in free trade, but I also believe in reciprocity; and at the same time I think if we were to shut our doors to Brother Jonathan it would bring him to his senses, so far as regards his raw products. At any rate, the company will not ask you again to spend £10,000 on such an undertaking; for I fully believe that the next time he has a big show, and we were to spend a further £10,000, Brother Jonathan would pass a law by which on no account would he allow diamonds into the United States, so that it will be better in future to leave Brother Jonathan alone."

Le Journal de l'Horlogerie says a new amalgam has been discovered which is a wonderful substitute for gold. It consists of ninety-four parts of copper to six parts of antimony. The copper is melted and the antimony is then added. Once the two metals are sufficiently fused together, a little magnesium and carbonate of lime are added to increase the density of the material. The product can be drawn, wrought and soldered just like gold, which it almost exactly resembles on being polished. Even when exposed to the action of ammoniacal salts or nitrous vapors it preserves its color. The cost of making it is about twenty-four cents a pound avoirdupois.

An Electric Elevator.

The accompanying cut represents a double-worm, direct-connected electric elevator, one of three recently made and erected by the Electrical Engineering Company, of 34 and 36 Main street, this city, for the Whittier Block, Los Angeles. They are said to



DOUBLE-WORM DIRECT-CONNECTED ELECTRIC ELEVATOR.

work to perfection. The motor, hoist and electric-controlling device, it will be seen from the cut, are all compactly mounted on common base plate which occupies a minimum amount of space. The elevator is entire controlled by pull rope or lever in the elevator cage. The controlling device is entirely enclosed in iron casing which protects it from dust and dirt, and is unique in this, that there is an entire absence of sparking at contact points. The motor is one of the company's latest multipolar type, slow speed and highly efficient.

TEN years ago the mines of California were at a discount in the East. Now they are at a premium, business men and investors realizing that, in these days of almost impossible profits in business, nothing equals in value a gold mine as a dividend producer. It is also noticeable that nearly all the really successful mining operations of the larger sort, the big enterprises, are projected by corporations. The day of the combine has arrived in mining as in other enterprises, and an aggregation of skill and capital alone starts and maintains the largest mining enterprises of the day.

Idaho's Mining Bill.

The new Idaho mining bill has become a law. It is in brief the general law with some changes to suit the mining conditions in that State.

Mining claims may extend to 300 feet on each side of the middle of the vein or lode. The locator must locate by posting on the surface a plain and permanent sign or notice containing the name of the locator, the name of the claim, length and width and date when the location is made, and by marking within ten days thereafter the surface boundary of the claim. Any claim so located is not, unless abandoned, subject to location by any other person for sixty days thereafter. Surface boundaries must be marked by substantial posts or trees not less than four inches square or in diameter.

Within sixty days after such location the locator must sink a shaft upon the lode to the depth of at least ten feet. Notice of location must be filed within ninety days thereafter with the county recorder or his deputy. An affidavit that the prescribed work has been done must be filed. County recorders must appoint deputies. Only citizens of the United States, or those who have declared their intention to be such, can locate a mining claim.

The bill has been endorsed by the leading mining men of that State.

IT is of daily occurrence to note the formation of a new mining company with "capital stock $1,000,000," or $5,000,000, or more. It is hardly necessary to say that there is often considerable difference between the amount of money actually subscribed and the "capital stock." A company with a "capital stock" of $1,000,000 may not have enough actual stock subscribed to buy a stock subscription book. Capitalization has nothing to do with the value of the stock or the property, though it is evidently supposed to influence opinion. There is no law against capitalizing a piece of property worth $150 at $10,000,000. Those figures are always nominal, and usually harmless. It is largely a matter of custom and should be "more honored in the breach than in the observance."

FROM the increased appearance in the columns of our interior contemporaries of a large number of applications for patent, it is evident that the recent advice of the PRESS is being followed. It is a good move at any time to secure a U. S. patent for a mining claim—it settles all possibility of litigation, and if it comes to a question of sale, a patented claim can in nearly all cases be sold easier than an unpatented one.

MINING AND SCIENTIFIC PRESS.

Office, No. 220 Market Street, Northeast Corner Front, San Francisco.
Take the Elevator, No. 12 Front Street.

Annual Subscription..... $3 00

Chicago Office..... CHAS. D. SPALDING, 320, 189 La Salle St.

Entered at the S. F. Postoffice as second-class mail matter.

Our latest forms go to press on Thursday evening.

J. F. HALLORAN.....General Manager

San Francisco, March 16, 1895.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Double-Worm Direct-Connected Electric Elevator, 161. Hercules Boiler Oil Injector, 168.
EDITORIALS.—De Beers Con. Mine Report; An Electric Elevator; Idaho's Mining Bill; Miscellaneous, 161. The True Reason; Miscellaneous, 162.
CORRESPONDENCE.—Drainage of Mines; Mr. McFadden's Exaggeration, 166.
ELECTRICAL PROGRESS.—Notable Discovery in Electricity; Miscellaneous, 165.
SCIENTIFIC PROGRESS.—Formation of the Rings of Wood in Trees; Miscellaneous, 168.
MECHANICAL PROGRESS.—Aluminum Alloy; "What is a Machine?" Important if True, 169.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 170-71.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 174.
MISCELLANEOUS.—Concentrates, 163. Pocket Hunting in California; Does Repeated Vibration of Iron and Steel Change Their Molecular Structure and Produce Rupture? 164. Coating for Iron Pipes, 165. Wanted to Put It in Escrow; Hercules Boiler Oil Injector; Personal; Obituary, 166. Consumption of Wood on the Comstock; Aluminum; Quantity and Price for Last Ten Years, 172. Canadian Lumber, 173. Recent Patents, 174. Coast Industrial Notes, 175.

CALIFORNIA annually expends $1,710,000 on its roads—"mainly in keeping bad roads in poor repair."

THE Manufacturers' Convention, which meets next Tuesday in this city, has the hearty co-operation and support of all who want to overcome the inertia of assuming that anything "made in the East" is necessarily better than if made here. The habit of sending East for nearly everything manufactured is a long standing one; but agitation, effort and business organization can overcome it.

"Two American prospectors in New Mexico have swindled an English representative of a British syndicate out of $50,000 by a salted mine." That is in every way reprehensible. The only place anything like that is admissible is in the national capital under administrative auspices, where it is the Americans who are swindled; the executive chiefs of the nation and the British bond buyers being the parties of the second part.

COMPARED with the "boom" in South African and Australian gold-mining concerns, the renewed activity in gold mining on this Pacific coast is as the murmur of a rivulet to the roar of Niagara. On Witwatersrand stock, though watered to the saturation point—the companies' nominal value being nearly £200,000,000 sterling—a profit of nearly 22 per cent on that enormous sum was secured in '94, and as new regions in that ancient land of Ophir are discovered and new reports of gold probabilities reach London, the rush for all kinds of mining shares in all kinds of places recalls the days of Laws' South Sea Bubble. Let it be hoped the cases are not parallel.

SECRETARY OF THE INTERIOR SMITH has ordered that all patenting of land to the Central and Union Pacific railroads be suspended till affirmative action is taken toward the settlement of the Government debt due from those roads. This must not be understood, however, as affecting the matter of mineral-land claims on the part of the S. P. Co. et al, whose applications for patents are now being published. Last Monday's Sacramento *Record Union* publishes a railroad application for over 200,000 acres, this being the latest of such publications observed. Miners in Trinity, Shasta and Siskiyou have only two weeks more—till the 30th inst.—to file protest at the Redding land office if they find their claims in the land listed at the land office at that place.

THE S. F. & S. J. V. R. R. is assured of a San Francisco terminal. The company calls now for sealed proposals, which will be received next Wednesday at the office, 321 Market street, for the delivery of ten thousand tons of 62½-lb. steel rails, best quality, on the wharf in San Francisco. Pattern to be submitted with bid. Bidders are also requested to make bids for 75,000 angle plates to fit above rail; also for 4800 kegs railroad spikes, size 5½x$\frac{9}{16}$; also for 150,000 railroad track bolts ¾x3½ hexagonal nuts. The first shipment of not less than one thousand tons will be required to be made within thirty days after time of placing the order. Shipments to be made thereafter at the rate of not less than two thousand tons per month until completion of contract. That sounds like business. Later on the company will want engines and cars. It is believed that no insuperable obstacles exist against manufacturing such rolling stock in this city. This is a matter that the Manufacturers' Convention, which meets next Tuesday, can with great propriety consider.

LIKE Colorado, Nevada is forced by existing conditions to change from a silver State to a gold State, and is equally fortunate in being able to demonstrate the existence of gold fields within its borders. In gold production there is no business jealousy or need of rivalry; the more gold the better. Nevada is desirous of attracting the attention of Eastern capitalists. In this regard a word may fittingly be uttered. Confidence is a plant of slow growth; some Nevada mining enterprises in days gone by were not wholly conducive to promoting that confidence in mining operations so necessary to the co-operation of the confiding capitalist. Now that the just attention of millions of Eastern idle money is turning to probabilities of profit in gold-mining enterprises, disposition to invest can best be augmented by strict attention to accuracy of statement and the absence of possibility of exaggeration in any particular case.

THE Butte, Montana, District Court recently rendered a decision which, if sustained, will have unwholesome effect. The owner of a mine made a contract by which the party contracted with was to operate his mine for a certain time, and make certain improvements with the privilege of buying it, a stated proportion of the proceeds of the ore to be paid to the owner, which would be credited on the price in case the mine was bought. If not, all the payments and improvements were to be forfeited. The contractor made improvements on the mine for which he did not pay, failed to buy the mine and turned it over to the owner with the improvements. The court held that he was the agent of the owner, under contract to operate the mine, and that it was subject to a lien for supplies and materials furnished at his request. If this hold good, many a mine owner will fear to bond or lease his mine with working privilege, lest he be run into debt against his will or beyond his financial ability.

THE Governor has vetoed Assembly bill 55. He considers it "unwise and injudicious legislation." It passed both houses as a measure of justice to all parties, and in recognition of the right of appeal on the part of the miners. The only desire was to give the miner the same rights possessed by other members of the body politic. The Governor further says in defense of his veto that the adoption of the bill "would deprive courts of their well-established powers." There is no court in California that would be deprived of a shadow of any inherent jurisdiction or just powers by the practical workings of the bill vetoed. The veto was sustained by a vote of 30 to 45. This does not end the matter. It only postpones the victory of right over might and the inertia of ignorance. The claims of the miners are too potent, the justice of their requests too manifest to be permanently set aside. Above and beyond Governors and courts is the greatest tribunal of all—public opinion—and it is fast being recognized that the great industry that is to-day the only prosperous one in the State cannot continue to be made the venting-ground of private spleen or ancient grudge. When the California Miners' Association met last November, the present executive made an address which spoke fair and promised justice to the miners. At the same time the Anti-Debris Association had a meeting in which they declared against anything the California Miners' Association convention might do or say. They didn't wait to see or hear what was said or done: they were "ferninst" the miners the same as the newly imported citizen was "ferninst" the Government. That was to be expected. But in the light of recent events, better treatment of such a manifest act of justice as Assembly bill 55 was expected from the chief magistrate of the State. The California miner doesn't ask favors nor does he expect partiality. But he has rights, no more, no less, than any other producer, and in this instance those rights have been denied him. As a matter of public policy, in the direct line of public interest, the veto is a mistake.

SECRETARY OF THE INTERIOR SMITH this week gave a point in favor of the Tyler Co., in its famous litigation with the Last Chance Mining Co., by ordering that a patent issue to the former. The main case is now being argued before the United States Supreme Court. The two mines are at Wardner, Idaho, the ground in dispute is worth $500,000; there is also involved $200,000 worth of ore taken out of the disputed area by the Last Chance, and claimed by the Tyler. The case has been in the Idaho courts for several years, was taken before the U. S. Circuit Court of Appeals in this city, where the Tyler people won. Then the Last Chance people succeeded in getting the Supreme Court to issue a writ of certiorari—something very unusual for the Supreme Court to do—and the case is now before the court of final resort. While this is pending in the court the Secretary of the Interior has settled a side litigation. Part of the Tyler claim overlapped the Last Chance. In its application for a patent it waived all right to the overlap. The Last Chance combatted the issuance of the patent because of the case being in the Supreme Court. Secretary Smith decides that cuts no figure in the matter, and that, as the Tyler waives all claim to the overlap, it shall have patent to the claim. In a third way the U. S. Government comes in in relation to this controversy. The First National Bank of Spokane, Wash., is one of the principal creditors of the Last Chance, and it, by reason of insolvency, is in charge of United States Controller of the Currency Eckles. So far, the Tyler has the best of it in the courts. Should the Supreme Court decide in its favor, that would of course be final. Should the decision be in favor of the Last Chance, that mine's attorneys say that would be practically final, because the Court of Appeals would then have to decide in their favor; but the Tyler attorneys contend that were a new trial ordered the result would depend upon the nature of the instructions sent back by the Supreme Court. Should the Last Chance win the suit the Spokane bank would be released from insolvency.

The True Reason.

Eastern papers, commenting on the increased activity here in gold mining, almost unanimously express doubt and fear regarding the "gambling mania," the "stock-jobbing proclivities," etc., of the industry, thus, singularly, showing their lack of understanding of the real facts. The natural turning of men to the mountains to get that which alone in these times has not depreciated in value, has no more to do with "stock jobbing" or "gambling mania" than the ocean steamship has with the gulls that soar and scream in her wake. It seems as if the "Eastern" press ought some time to be able to disassociate California gold mines from the idea of stock-market fluctuations. Those mines are rarely listed; their stock is not at the mercy of street manipulators; the ups or downs of shorts and coverers do not affect the value, and the real reason for the increased activity in California's gold-mining industry is because there is no better paying occupation in the world to-day. Gold is universally demanded; it will buy more of anything for sale than ever before: hence, naturally, men seek it with more ardor than ever before. With wheat at 50 cents, butter at 15, prunes at 4, wine at 12½, raisins at 3, eggs at 8, and everything else in the agricultural, horticultural and dairy world at like prices, the fact that gold is still worth $20.67 an ounce; that the market cannot be glutted, and that increased new processes make profitable the working of low-grade ore, attracts the attention of business men to the working of gold mines as a business proposition—a legitimate investment; and once realizing this fact, they of course investigate where the gold is and where the best experience has produced the best methods, and where the most likelihood of sure returns can be found. It is because of these facts, and not from any yearning for "gambling mania" or "stock jobbing," that Eastern men are now securing valuable gold properties in this State.

Concentrates.

THE exact value of a ton of gold is $602,027.23.

THERE will be no "suspension of assessments" for the current year.

LOS ANGELENOS are bonding properties in the new Mountain Springs district.

THE Gold Basin mining field is now the most extensive gold-producing region in Arizona.

THE "Alturas Gold Company," of Loadon fame, has been finally "wound up" in that city.

ALASKA papers say five times as many immigrants are going to the Yukon as can find a living.

ARIZONA ranks third in the production of copper, being surpassed by only Michigan and Montana.

THE English owners of the Twin Lake Placer Co., Colorado, have declared a $46,500 dividend for '94.

COLORADO proposes to hold an International Mining and Industrial Exposition in Denver next year.

THE Banner mill at Idaho City, Idaho, closed down last week for the season. It will resume crushing in July.

IT is expected that the present number of miners in the Pittsburg, Grass Valley (20), will soon be doubled.

THE Grass Valley *Union* says: "The new tariff law is having a beneficial effect abroad as well as at home."

MR. H. S. ALGAR is the manager of the Northwestern Mining Bureau, recently established at Seattle, Wash.

THE Le Roi is opened to a greater depth than any other mine in Kootenay. The working shaft is 360 feet deep.

THE Bi-Metallic Company at Phillipsburg is treating about 300 tons of ore per day and has nearly 500 men at work.

THE Oregon & California Mining and Milling Co. expect to start the mill upon their property near Henley shortly.

ROBBERS scared away the watchman of the Daisy Hill mine at Grass Valley last Tuesday night and looted the works.

THE James Watson hydraulic gold mine, near Igo, Shasta county, has been issued a permit by the Debris Commission.

A BILL is pending in the Nevada Legislature providing for the consolidation of Storey, Ormsby, Lyon and Douglas counties.

PARK CITY, UTAH, ores—almost exclusively lead and silver—can be handled with profit, even with silver selling at sixty cents.

NEVADA COUNTY papers report gravel $3 to the pan, 200 feet wide and four feet deep, at the Harmony mine—a regular bonanza.

FIRE in the Old Abe mine, near San Antonio, New Mexico, last Saturday, proved fatal to eight poor fellows who perished near the shaft.

IN Cripple Creek and Leadville, the two best mining camps of Colorado, the leasing system is the present favorite method of development.

THE incline on the Queen, Golden Cross M. & M. Co., Hedges, Cal., is down 450 feet. Seventy men are employed at the mill and mine.

SEVERAL experienced Nevada county miners have gone to South Africa and British Columbia, where good positions have been assured them.

THE Boston & Montana smelter at Great Falls is now running at its full capacity. For some time past it has been operated with a reduced force.

A PROPERTY OWNER of West Point, Calavoras Co., recently advertised for a lawyer to locate in that lawyerless town. The want was immediately supplied.

THE Rio Grande Western Ry. Co. is still boring for water at Salt Lake City, Utah; and has secured a depth of 1073 feet and appears to be getting a long well.

DISCONTENT and distress in Sicily have been increased by the closing of many sulphur mines. More than 25,000 miners have been thrown out of work recently.

THE Rico, Col., Smelting and Refining Co. has incorporated; capital stock, $100,000; directors: A. B. Roder, D. B. Ellis, F. T. Osgood, J. E. Searles and E. N. Senrles.

THE Debris Commission has granted a permit to operate to the James Slater mine, Brownsville, Yuba county, as soon as a restraining dam has been constructed and approved.

THE Snow Shoe mine, near Thompson Falls, Montana, has been sold to H. C. Walters of Spokane for $100,000. A 100-stamp mill will be erected on the mine in the spring.

ENCOURAGED by the success of the Wall street bond syndicate with Government representatives, gold brick swindlers are displaying renewed interest in their old business.

THE new town of Gaylord, Montana, where the Parrot Company intend building their smelter, is about four miles from Whitehall at the base of a spur of the Tobacco Root range.

CAPTAIN DE LAMAR is said to have invented an improved cyanide process, which he will test at the new mill recently built on the Monitor and Jim Crow gold mines at Ferguson, Nevada.

THE Hite Gold Mining Company has incorporated. Directors—William S. Chapman, G. H. Mangels, J. E. Mason, A. E. Shattuck and George C. Munro. Capital stock, $500,000; all subscribed.

THE Nickel Plate Mining Company is a new organization at Caldwell, Idaho, that has now under construction a large boat for the purpose of dredging Snake river to test a new gold-saving machine.

THE gold output of the Witwatersrand, S. A. district, seems to have reached high-water mark in December '94. The January output was 177,463 ounces—4641 ounces less than that of the preceding month.

THE Tacoma, Wash., banks have begun to take British Columbia coin from customers at par. The object is to increase the provincial trade with that city, and this it already has begun to do. Reports reach the banks, however, that the merchants, or at least some of them, are still discounting the foreign coin. For instance, a merchant may take a British Columbia 25-cent piece for 20 cents and deposit it in the bank, receiving 25 cents therefor, and making 5 cents, or 25 per cent, by the operation. If this is continued the banks say they will not accept the coin at par.

THE California Debris Commission has before it a large number of petitions for the resumption of hydraulic mines in various northern counties. Next Monday eight applications to resume hydraulic mining will be heard.

THE Albuquerque, Arizona, *Citizen* libels the reputation of territorial legislators in instancing the era of cheap prices by the allegation that "a majority in the lower house of the Legislature was recently bought for $87."

W. H. CLARK claims that his new mill in Butte, Montana, can treat every class af gold ore except tellurium. He asserts that all gold is free in ore except in tellurium ores, and backs his judgment by a $150,000 investment.

THE Anaconda, Montana, *Standard* claims to have inside information that the Burlington will be extended to Butte this year, connecting with the Butte, Anaconda & Pacific. The latter will also be built to Boise, Idaho.

THE Juneau, Alaska, *Mining Record* issues a souvenir edition for February that would be a credit to any community in the country. It is possessed of artistic merit and contains much of merit regarding the mines of that Territory.

THE general public does not hear of one mining deal in ten. The parties to the transaction, especially if it be a small one, usually give out no information. A complete record of the mining transfers made in the State for one day would be interesting.

THE "lost Peg Leg mine" has been discovered again, this time by Mr. Chas. Achterman in the Cahuilla reservation, Riverside Co. It is alleged to be "in a saddle on the San Jacinto range of mountains," with its headquarters evidently where its headquarters ought to be.

L. C. BRAGO has changed the National City, San Diego Co., reduction works into a cyanide plant, and is treating the tailings by that process. These tailings are from rebellious ores from Cedros islands, and contain from $10 to $20 per ton. The company now has 5000 tons of tailings which will be worked.

AT the Gold Ridge mine, near Graniteville, Cal., last week, George Dey and John Rennie were working in a drift and were putting in a blast. One of the caps exploded and fell in the box of caps, causing them to all explode. Dey was killed outright and Rennie injured so badly that he is not expected to live.

H. L. CHILDS, of Montana, and some New York and Newark, N. J., men, have incorporated the Syndicate Gold Mines and Mill Company, with a capital stock of $5,000,000. The articles say that the operations of the company are to be carried on in any part of the world. The principal office is to be at Virginia City, Montana.

THE coroner's jury has found that the gas explosion in the White Ash, Colorado, mine on the 27th ult., which killed twenty-four men, was due to lack of air, one air shaft being obstructed by water. Heavy damage suits will be instituted against the company by relatives of the victims, unless a compromise is effected.

A SYNDICATE of Denver men have bought a placer claim on Four Mile, Carbon county, Wyoming for $100,000. It was formerly owned by John C. Davis of Cheyenne and A. Kendall of Rock Springs. The purchasers will expend a quarter of a million dollars in developing the property. This is said to be the largest mining deal ever recorded in Carbon county.

THE Katie mine at Basin, Montana, has been attached for $73,000 by a number of creditors, among them being the Western Iron Works, which has a claim against the mine for new machinery furnished. This property is operated by the Glass Bros., one of whom is now in the East for the purpose of raising money with which to place the enterprise on its feet again. The Katie is considered one of the best properties in Basin.

"A PROSPECTOR brought fourteen pounds of ore into The Needles recently which netted him $4000. It was obtained from a quartz lead within sixty miles of that point." This is clipped from a city daily of the 5th inst. Fourteen pounds avoridupois is about 202.5 Troy ounces: thus the *ore* netted a fraction over $19.75 per ounce. When it is considered that the gold coin of the U. S. is only worth $18.605 per ounce, at fine gold prices, it is evident that this is pretty good ore.

THE Shasta *Courier*, referring to the time it was first published, March, 1852, says $50 octagonal coins were then plentiful, $20 pieces common, and $10 and $5 pieces rated as small change, while $2.50 and smaller coins were considered what is now called "chicken feed," and gold dust by the ounce was a legal tender for bills anywhere. The same may be said of Yreka in 1852-3-4-5. Ten dollars a ticket was the price to a ball or dance, 25 cents for a drink or smoke, and a dollar for a meal.

THE Land Department has recently decided: First—A settlement claim that will defeat the operation of a railroad grant must be of a character capable of being asserted by the party in possession under the settlement laws. Second—If having been held that a placer location of 160 acres by an association requires a discovery of mineral on each twenty acres, opportunity will be given the locators for a further showing where, under the rulings in force at the time of location, a single discovery was deemed sufficient.

SINCE the decision of the Department of the Interior, sustaining the claim of John H. McBride to 120 acres of school section 16 at Tacoma as gold-mining land, there have been six more filings on the already well-covered section. Three of these claims were filed lately. Rudolph Martin claims twenty acres; Louis Drexler claims ten acres, and Caroline Miller claims twenty acres. It is said the claimants are acting for other parties. Each location states the land is to be used for placer mining, which is very unlikely.

THE old days of the Mooneyville excitement near the Cliff House are recalled by the renewed activity in beach-sand gold mining on the ocean shore southward from Sutro Heights. There are four separate parties now at work, scattered along to the San Mateo Co. line. The sand is said to yield $2.50 per ton, and one party reports an ability to treat twenty tons a day. Several attempts through the years have been made to make these sands pay. They are almost limitless in quantity and contain gold, the same as in a hundred other localities along the California and Oregon coasts. Banta & Wink, of Port Orford, Or., write to the MINING AND SCIENTIFIC PRESS that their system at that place has proved to be a great success. They decline to give the formula of their secret chemical process, but claim they do not use any quicksilver. The workers at Mussel Rock and elsewhere below the Cliff House use the amalgamation process.

A PROPOSITION is before the Nevada Legislature to amend the Constitution so that patented mines can be taxed. The first Constitutional convention held in Nevada provided for the taxation of mines. That Constitution was overwhelmingly defeated and the convention which framed the present Constitution eliminated that clause and exempted mines and mining claims from taxation. The people ratified the Constitution and if they are now in favor of taxing patented and unpatented mines, that can be ascertained without much expense to the State by submitting the proposition to the voters at a general election.

THERE has never been a time in the previous history of Montana when so much interest has been taken in mining matters, says the Marysville *Messenger*. Even some of the old fellows who have stuck to their mines like grim death to an African, have given up the idea of becoming millionaires without work: and, being impecunious, have decided to bond some of their prospects and allow them to be developed. Judging from personal knowledge, and that gained from the press and individuals, we are confident that fully double the number of mines will be operated during the year 1895 than there were in the year 1894.

HETTY GREEN, the eccentric woman who possesses so many million dollars, is the owner of a mine near Sutter Creek, that was the original mine where one of California's wealthiest men got his start in life. The timbers took fire and ruined the shaft for further use, without the expenditure of a large sum of money, and the mine was transferred to the departed Mr. Green in payment of a claim. Although it is a valuable property, not a cent has been taken out of it for years, and Mrs. Hetty will neither work it herself nor permit any one else to work it. It is said that the present Assessor of Amador county contemplates raising the assessment on the property from $8000 to $100,000 and compel the lady to take some interest in her California property.

CONCENTRATION is having quite a boom at Idaho Springs and Central City, Colorado, and every mine owner is trying to get his ore to this kind of treatment. It is beginning to be understood that the ores are not sufficiently free milling to stand that method of milling. The Fisk made a test of ores at a concentrator in Idaho Springs last week and, it is said, got a return greater by forty per cent than the same ores bring at the stamp mills. A number of new mills are planned for Idaho Springs and will be built during the summer. The Newton, a new stamp mill, has been enlarged by the addition of a concentrating plant of fifty tons daily capacity, and the movement for concentration is so strong that there are more offers of ore than a mill of three times the size can handle. Many properties which could otherwise work are consequently forced to lie idle.

"A THOUSAND DOLLARS A DAY" is the name of an interesting fancy written by Miss Adelina Knapp, of this city, and published by the Arena Company, of Boston. The story tells of the effect of a general distribution of the wealth of the Golconda mine, in Arizona, throughout the United States. The mine being fabulous in extent and inexhaustible, $1000 in gold was to be given to every man and woman over eighteen years old every single day, and paid at the banks. The first day there was a thrill of delight at receiving the shining coin. Men settled up, or promised to settle, and made new purchases, and business boomed. In three days all work stopped. There were no policemen to guard the gold, because nobody wanted gold, nor would take it as a gift. What people wanted was bread, meat, cars to run, a sexton to attend to a burial perhaps, a cook, a carpenter. In time the mint stopped coining, gold was used for the arts and manufactures only, and labor was the only commodity for exchange. The capitalists and politicians, even, took their places and their turns at work.

A WOOD PILE in Lead City, S. D., belonging to the Homestake Gold Mining Company, is composed of timbers about the size of railroad ties, which are used in supporting the walls and roofs of the drifts and tunnels of the mines. A narrow-gauge railroad brings the logs, which have been sawed flat on two sides, to a point on the mountain slope about 600 feet above the valley, and they are then thrown into a wooden chute about four feet wide and two feet deep. The inside surface is kept smooth and slippery by a small stream of water. If the logs were allowed to run directly to the ground, they would speedily excavate an enormous hole besides damaging themselves, so the lower end of the chute is curved upward, and the logs leave it at an angle of about 60° with the horizontal and rise from 150 to 200 feet in the air, turning over and over, and finally landing on the enormous pile already there. A useful fact in connection with this method is that the logs sort themselves in the pile according to their size; the heavier ones, having a greater momentum, are all found at the side farthest away from the chute.

ESMERALDA CO., NEV., will have a little stir, by reason of a deal made this week, which involves about $2,000,000. Since the days of the Northern Belle the accumulated tailings have been a mass of unrealized wealth. The Holmes Mining Co. has contracted with an English company, disposing of about 400,000 tons of those tailings for fifty cents per ton, and to deliver about 700,000 tons low grade ore at the rate of $3.50 per ton for all ores whose assay value is fifteen ounces per ton. Ores running between fifteen and twenty ounces, worked by the English Co., are to pay the Holmes Co. twenty-five per cent of the battery assay value. All ore assaying above twenty ounces per ton is reserved by the Holmes Co., to be worked at the Candelaria mill. The English Co. will "clean up" the Belleville and Candelaria mills, receiving therefor forty-five per cent of the result. The latter is to begin within thirty days, and the proposed plant for working the tailings is to be in operation within four months from date. All settlements are to be monthly. It is estimated the erection of the plant for working the tailings will involve a preliminary expenditure of nearly $250,000.

Pocket Hunting in California.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS, M. E.

As the distribution of gold in veins of the pocket type is very irregular, those unacquainted with this class of gold mine would very naturally be led to inquire by what method the pocket hunter is enabled to discover his bonanza.

Pockets and pocket veins are found principally in two ways: By a systematic search known as "surfacing," and incidentally as the result of placer mining. Doubtless pockets have not infrequently been found by means of rich float quartz lying upon the surface almost in place, or at least not far removed from the original deposit, but these occurrences are more rare, and their discovery is the result of good fortune rather than anything else.

In the pocket mining regions of Mariposa and Tuolumne counties the prospector is not guided by any topographical feature or by any particular indication on the surface, unless, indeed, he be on the line of a well-known vein or series of pockets. His first venture is usually of the haphazard sort. He simply "goes prospecting" and selects a place where no one has been before and inaugurates a system of search. He usually chooses a slope, though the flats are not neglected. The method of investigation undertaken is called "surfacing." He begins by digging a series of small holes along the slope. These holes may be five or ten feet apart. The soil, rocks and other material taken from each hole is washed separately to determine the presence or absence of gold. Presuming that gold is found in some of these holes, it is usually noticed that those places showing gold are contiguous, while on the outer limits the soil tested shows little or no gold.

Having now determined the width of the gold-bearing hillside deposit at this particular level, the indefatigable prospector opens a second series of holes higher up the slope and immediately above the first. As a rule he finds more gold and he notes that the width of the gold-producing area is not so broad as at the lower series of holes. This is at once encouraging, and he hastens to make a third series of test holes still higher up the slope. As before, gold is found, but distributed across a narrower field than at the second series of holes. The gold-bearing area, as determined by the labors of the prospector, is assuming the form of the triangle with its apex pointing up the slope. Continuing the operation in the manner described, the pocket is at last found at the very apex of the pyramid, though possibly some distance below the surface under the loose soil imbedded in solid rock, or perhaps it may be found mingled with broken rock which has moved but little from its original position.

All observing persons have noticed that rocks rolling down a slope from a common point spread out in the shape of a fan, diverging more and more as the distance from the point of starting increases. Gold freed by nature from its matrix in the rocks distributes itself over a slope in exactly the same manner. The pocket hunter is well acquainted with this simple principle and an experienced prospector, after making two series of holes as described, can often locate very closely the source of the gold found in surfacing. Usually the gold is coarser near the pocket than at a distance from it; it also shows increasing roughness as the pocket is approached. All these indications are noted with care by the pocket hunter, and he acts in accordance with the indications.

A simple case with a successful termination has only been cited. The pursuit of the elusive "pocket" is not always so easy nor as successful as might be inferred. It is often a perplexing and discouraging task. Landslides of ancient origin; great depth of soil; interfering rock reefs which have influenced the direction of the float; the erosion of gulches and a score of other things combine at times to worry and defeat the prospector. A scarcity of water, which is not uncommon, only adds to the vicissitudes of pocket hunting. The several samples of dirt taken from the little holes on the hillside must be sacked and kept separate, and carried sometimes several miles to water, or down into a deep canyon, through high brush, over ragged rocks to a point where water can be obtained.

Considering all the drawbacks to pocket hunting, together with the uncertainty of the result, it is not hard to believe that pocket hunters must possess a most sanguine temperament.

A great many pocket veins have been discovered by placer miners, who have been led, foot by foot, directly to the source of the gold found in the gulches. The miner having worked his rich diggings up to a quartz vein and finding on passing it that the placer contains less gold or none at all, at once concludes that the source of his gulch gold is the quartz vein over which he has just passed.

Prospecting the vein quartz and finding no gold, his next conclusion is (basing his judgment on experience) that the pay is "spotted," or, in other words, a "pocket vein," for it not infrequently occurs that a bonanza is not at once discovered on the vein—those pockets which had supplied the gulch having been entirely eroded.

Then the experienced pocket hunter shows his skill. He begins a systematic search for "indications." He strips the vein, if it is not already well exposed, in search of a "crossing," the nature of which was described in a former paper on this subject. A "crossing" is a fissure, large or small, intersecting another vein at an angle. For instance, assuming the main vein to strike north, dipping 45° east, a fissure having a nearly east and west course and dipping anywhere from 45° to 90° either north or south and intersecting the main vein, would be called a "crossing."

It may be that the conditions at the surface are such that the miner does not consider it the best plan to open the vein longitudinally in search of a "crossing." His alternative is to sink a shaft on the vein in search of a "gold seam," which is the other essential for a regular pocket mine. A "gold seam" is also a fissure intersecting the main vein at any angle. It is usually small and has a strike nearly parallel with the vein. "Crossings" and "gold seams" do not conform to any rule as to their angles of intersection with the main vein, nor in their angles of dip. It is evident that a "crossing" striking west and standing perpendicular and intersecting a quartz vein striking north, dipping at any angle, will become a "gold seam" if the "crossing" assumes a dip approaching the horizontal; so they are simply relative terms, but the relation is not constant, the only requisite being that both the "crossing" and the "gold seam" shall intersect the main vein, and also that they shall intersect each other. It is at the point of intersection of these three planes, viz: the vein, the "crossing" and the "gold seam," that the bonanza is found, if found at all.

These seams are the guide to the pocket hunter in the majority of cases, but it appears that there are exceptions to this rule and that pockets do sometimes occur under other conditions.

About a mile from Big Oak Flat, in Tuolumne county, is a pocket mine known as the Silken. It has produced thousands of dollars from a small space, comparatively speaking. The pockets have all occurred within a well-defined area, in the form of a shoot thirty feet long and about four feet wide at the middle. This shoot pitches northward along the vein at an angle of 45°.

The vein strikes north, dipping west at about 40° near the surface, but becomes flatter with depth. It occurs in slates which strike east and west, dipping southward at 80°. The vein cuts directly across these slates. Along this vein "gold seams" running nearly parallel with it cut down from the hanging wall, making an intersection with the vein. The miner follows this line of intersection. "Crossings" are found parallel with the slates, cutting down through the vein and "gold seams," and deposits of gold are almost invariably found at the intersection of the three planes. These pockets range in value from $10 or $20 to several hundred dollars. The owner of this mine told me that he had averaged $150 a month ever since striking the pay shoot to which the pockets are confined. He worked alone most of the time, six days a week and about six or seven hours a day. The Silken is a distinct type of mines of the pocket class. It is not often, however, that the pockets occur within well-defined limits, as appears to be the case here.

There is another very interesting little mine not far from the Silken; on the same hill, in fact. It is known as the Ophir. It is rather an unusual deposit, but it has paid well for the small amount of work performed upon it. The Ophir mine is one mile northwest of Big Oak Flat. The vein, which is small, varying from a seam to two feet in thickness, lies nearly flat, intersecting slates which stand perpendicular, striking 15° west of north. The principal development on the mine at the time I saw it was a tunnel 170 feet in length, that had been driven on a fault which strikes across the slates at a low angle, but is also perpendicular. This slip, being younger than the flat quartz vein, has fractured it, that portion of the vein and the inclosing rock lying to the north of the slip having dropped down from one to three feet. It is in the mass of crushed slate and fragments of quartz lying between the fractured ends of the quartz veins that the gold has all been found. Over $4000 had been taken from this 170-foot tunnel in less than two months by two men. In addition to the coarse gold, obtained by pounding up the selected material in a hand mortar, considerable mill rock is also obtained which is worth over $100 a ton.

Bald mountain, near Sonora, in Tuolumne county, is a treasure vault of bonanzas. It has already produced hundreds of thousands of dollars and is still the scene of active mining operations. Most of the mines are of the pocket class. I had the opportunity of making an inspection of one of these mines near the base of the mountain near Shaw's Flat, known as the Louis Page mine, famous not only for its richness, but also for the great brilliancy and extreme beauty of the specimens of crystallized gold and telluride of gold and silver (petzite).

The Page fissure is from a seam to three feet in width and is usually accompanied by more or less quartz. It strikes northeasterly through metamorphic rocks of varying character and altered eruptives—diorite or diabase, diorite-porphyrite, black argillaceous slate and a sandy mica slate, hard, dense quartzite and felsitic dike rocks. A dike of light-colored rock of felsitic texture is found throughout all the workings of this mine. In places it is not over an inch wide; in others it has a width of several feet. It sends numerous branches off into the slaty rock of the walls. In some instances good-sized nuggets of gold have been found attached to the dike rock. A dike rock of similar appearance was found in this mine occupying a horizontal position. It appeared to have no influence on the gold. All of these dikes are older than the fissure in which the gold occurs, as the crevice frequently intersects the dikes and displaces them.

As usual, the gold in this mine occurs at the intersection of "crossings," "gold seams" and the vein proper, either in the quartz or in the wall rock near the intersection. The best results, I was informed, were found where the "gold seams" were nearly horizontal and just at the point where a nearly vertical "crossing" intersected both vein and "gold seam". There have been exceptions, I am told, in this mine, as gold has been found at the intersection of a "crossing" and the main vein. On the other hand, all of the necessary conditions—vein, "crossing" and "gold seam"—have been found, but no gold. What the real cause for this is no one has yet been able to satisfactorily determine.

This mine has a record of production exceeding $165,000. The lessees who were operating the mine at the time of my visit had been engaged for more than two years in driving the lower tunnel into the vein through rock which sometimes cost nearly $100 a foot. They simply demonstrate what has already been said—that it requires a sanguine man to make a successful pocket miner.

The Saratoga mine, a mile north of Sonora, is also a pocket mine with a record of production exceeding $100,000. The vein, from two inches to four feet in width, strikes north 50° east, dipping 70° northwest. It is a simple fissure cutting the formation, slates, quartzite, limestone and older dikes. The strike of this formation is north 25° west with a dip to the northeastward. Although this fissure cuts several varieties of argillaceous quartzose, magnesian and calcareous rocks, no gold is found in the vein adjacent to any of them except the black argillites. Accompanying the vein is a dike of felsitic rock.

The fissure is also a plane of displacement. The successive formations of the footwall side are found repeated in their respective order on the hanging-wall side thirty feet distant to the southwestward. It appears to be an example of the "thrust" type of faulting. The walls of the fissure are deeply striated in places.

All the gold thus far found in this vein has been at the intersection of "gold seams" and "crossings," but then only when the crossings occur in the slates. In this respect the Saratoga mine resembles the Bonanza.

The mines thus far described are all in Tuolumne county and for most part are similar, and exemplify to a nicety the theory of the pocket hunter that gold occurs at the intersection of three planes, one of which is the quartz vein. Similar mines occur in Mariposa county. There is a belt of pocket mines running through that county which are somewhat different in character, and will be described in another article.

Does Repeated Vibration of Iron and Steel Change their Molecular Structure and Produce Rupture?

In an article by Mr. Rickard upon "The Limitations of the Stamp Mill," which appeared in these columns some time ago, the statement was made that "vibration under all conditions will crystallize iron." This statement was criticised and as a result of the criticism a very interesting discussion has been running in the *Transactions of the American Institute of Mining Engineers*, a portion of the discussion having been published in Volume XXIII, page 143, and 557, while a continuation of the most interesting part of the same will appear in the Vol. XXIV which will be published in about three months. This subject is of interest to engineers. The following summary of the discussion is from advance pages of the *Transactions*:

Mr. Philip Argall holds that intense vibration under any condition will eventually crystallize iron and holds that such crystallization is simply a question of time. While admitting that the authorities differ upon the possibility of cold crystallization of iron, he believes it to be a settled and undisputed fact that vibration in the presence of heat will crystallize iron, quoting in support of the latter proposition Messrs. Blaxam & Huntington, Hall & Howe, quoting also in support of the former opinion the opinion generally prevailing in many text books and writings upon the subject.

He also cited some experiments and conclusions of

(Continued on page 172.)

Electrical Progress.

Notable Discovery in Electricity.

The year 1894 was not remarkable for epoch-making discoveries in science, but was busily occupied in the prosecution of familiar lines of research, with useful applications of existing knowledge as the chief result. Nevertheless something has been done to widen the intellectual vision and stimulate thought in new directions. Perhaps the most striking original work of the past year was Philipp Lenard's application in England of Hertz's discovery that metallic films are transparent to the dark rays issuing from the negative pole in the case of electric discharge in a high vacuum. Mr. Lenard closed one end of a vacuum tube with an aluminum film thick enough to resist atmospheric pressure and studied the rays after passage through the metal. The air outside was seen to glow faintly. All the ordinary phosphorescent effects produced by Crookes in a vacuum were thus readily produced in air. These rays from the negative pole, though not affecting the eye and producing no sensation in the skin, are yet photographically active, and to the tongue and nostrils have the taste and smell of ozone.

Unlike the rays of ordinary light, they cannot pass through quartz plates, but do not pass through metal films which are opaque to light. In respect to air or gas their behavior is equally novel. Ordinary light passes through a gas as if it were a homogeneous medium and becomes dispersed or makes its path visible only in case there are solid particles, such as dust, floating in the gas. But these rays from the negative pole, or "cathode rays," affect the gas molecules as if they were solid particles floating in a continuous medium. In other words, all gases, however transparent to ordinary light, are turpid to cathode rays, and the degree of turpidity depends wholly upon the density or mass of the gas molecules present, irrespective of their chemical character. Oxygen, for example, under a reduced pressure that brings it to the density of hydrogen, is as transparent as hydrogen, while hydrogen, if brought by pressure to the density of oxygen, becomes as turpid as oxygen.

The cathode rays traverse a perfect vacuum with facility. After passing through the aluminum screen their radiation in air stops at a distance of eight-tenths of an inch, but in hydrogen it extends to four inches and in a vacuum to fifty-two inches. While the rarest gas disperses the cathode ray into a blur, as a fog disperses an ordinary ray, its movement in a vacuum is in a straight line. But a magnet brought near deflects it. The question of the nature of matter is raised by some of Mr. Lenard's experiments, the experimenter being of opinion that the fact that every gas molecule acts as a solid obstacle to the passage of the cathode rays is a proof that the molecule is only "a function of the ether itself"—virtually that there is no matter, unless the name can be given to ether, a substance that eludes all tests. Prof. J. J. Thompson, on the other hand, finding that the rate of propagation of these phosphorescence-producing cathode rays is much less than that of ordinary light, but about one hundred times as great as that of the hydrogen molecule, solves the difficulty by assuming that electrified gaseous molecules, rather than the ether, are the seat of this mysterious force.

A practical utilization of the cathode rays has been in the Ebert luminescent lamp. The inventor states that a serviceable light can be obtained by means of his lamp with an expenditure of one-two-thousandth part of the energy consumed in the acetate unit lamp. Just what weight is to be given to his claim is in doubt, but it is evident that we have in Hertz's discovery and Ebert's lamp a promise of a new method of electric lighting vastly cheaper than those with which we are at present familiar.

It is stated that two new companies, in addition to the one now deriving power from Niagara Falls, will put in plants there, and will furnish power to industrial establishments in Buffalo. Prices as low as $2 or $3 per year per horse power are talked of by one company, which already controls a canal from which power for a number of factories is derived, the waste water falling over the cliffs. It is expected that by simply fixing pen stocks to the face of the cliffs, placing water wheels at the bottom and turning this waste into them, about 30,000-horse power will be available.—American Machinist.

THE operators of the Bakersfield electric light plant are experiencing no little annoyance of late by the soft wires between the commutator and armature burning out. Sometimes they do not last more than one night. Up till recently nothing of the kind had happened for four years. No satisfactory reason for it can be found. Information from various places says that similar trouble is occurring to other plants.

MAJOR JEWETT, of Buffalo, in a speech at a recent banquet, said that among other delightful things which Niagara will do for Buffalo are: Shovel snow, wind the clocks, run mother's sewing machine, bathe baby, pound beefsteak, feed the canary, cut the grass, boil eggs and take a hand at whist.

ACCORDING to the daily press, L. C. Pressley, of this city, has developed a device for "producing electricity direct from heat." Turn off the heat: turn on the light.

Coating for Iron Pipes.

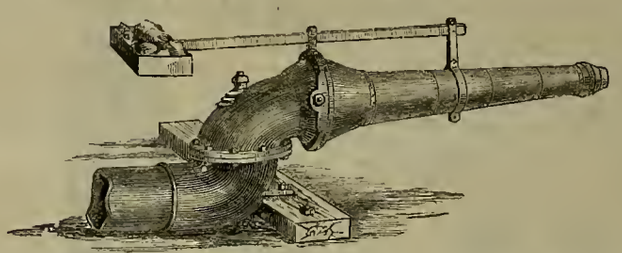
The best coating for iron pipes that can stand the heat at 250° or more is made with a good asphalt lacquer laid on thinly. In order to tint this, an oxide in pulverized form of any metal is added; for instance, if good zinc or white tin is mixed with the asphalt it gives a gray shade, while red lead gives a brownish tint. If the asphalt is laid on thinly and "tin bronze" (the well known white bronze in the form of powder) is lightly dusted over it, it gives a coating of very pretty shade. A cheap and durable coating for steam pipes made of iron is somewhat difficult to find, especially if the coating is designed to protect the pipe against rust. It is difficult to put a durable coating on surfaces that have to withstand great changes of temperature, but in this case, when rust of the pipes is to be feared, it would be better to refrain from painting the pipes at all, and to zinc them instead. When they are covered with zinc, the fine pores of the iron are completely closed, which is not the case with painting. A good zincing of the pipes half way up also gives a pretty steel-like gray tint. To produce a red color the pipes, after being zinced, could be coated with some lead paint. If it is not considered advisable to use a zinc bath, a coating of red lead or zinc powder oil and seccative can be used instead. But however good these may be, they would not be successful in the case referred to in the question. If any oil paint should be used, care should be taken that this adheres properly to the metallic iron surface; consequently a thorough cleansing is necessary. If the red lead or vermillion referred to is employed, care must be taken that it is not adulterated. The good genuine red lead (Paris red) is a mixture of super oxide of lead with litharge and not with the ordinary iron vermillion (English lead); the latter consists of oxide of iron and peels off far more easily than the first-mentioned color. To hinder the peeling a light coating of lacquer is, in several cases, brushed over the paint, but this, of course, increases the expense of the operation.

INVENTORS, Take Notice!
L. PETERSON, MODEL MAKER,
226 MARKET ST., N. E. Corner Front (Up Stairs), SAN FRANCISCO. Experimental machinery and all kinds of models. Tin and brasswork. All communications *strictly confidential.*

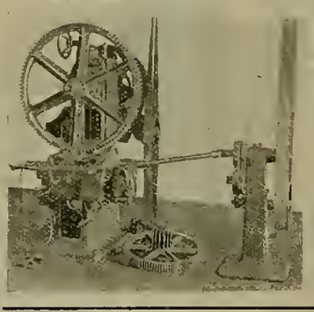
Selby Smelting and Lead Company,
416 Montgomery Street, San Francisco.
Gold and Silver Refinery
—AND—
Assay Office.
HIGHEST PRICES PAID FOR GOLD, SILVER AND LEAD ORES AND SULPHURETS.
Manufacturers of
BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.
Also Manufacturers of
STANDARD SHOT-GUN CARTRIDGES,
Under Chamberlin Patent.

RUPTURE!
IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

TUBBS CORDAGE CO.
(A CORPORATION.)
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. Extra sizes and lengths made to order on short notice
611 and 613 FRONT ST., San Francisco, Cal.

IMPROVED FORM OF HYDRAULIC GIANTS.


The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.
JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.



GEAR CUTTING
A SPECIALTY.
Fine Work at Bedrock Rates.
SPUR, BEVEL, and WORM GEARS of any pitch or size up to 50 Inches.
<<<< TAPS AND REAMERS GROUND. >>>>
Experimental Machinery and Repair Work of all kinds.
P. T. TAYLOR & CO.,
523 Mission Street, - - San Francisco, Cal.

BOILER OIL INJECTORS

Progression is the order of the day.
Attach one of "LUNKENHEIMER'S" to your boiler and you will be astonished with results. The only Injector made that will entirely free your boiler of scales.
Practical in Construction; Simple in Operation.
Provided with a visible feed. Sizes ½ pint to 1 gallon. Specify and insist on "LUNKENHEIMER'S" and you will get the best. Consult Dealer. New Catalogue of Superior Steam Specialties, gratis upon request.
THE LUNKENHEIMER COMPANY.
FACTORIES — CINCINNATI, O.
NEW YORK STORE, 81 JOHN ST.
EUROPEAN STORE: THE LUNKEN VALVE CO. 35 Gt DOVER ST LONDON, S.E.

FRANCIS SMITH & CO.,
—MANUFACTURERS OF—
SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.
Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.
130 BEALE STREET, SAN FRANCISCO, CAL.
Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Drainage of Mines.

TO THE EDITOR:—I am pleased to see that this, the most important operation in mining, is now receiving the attention it has so long deserved, and that great efforts are being made in various ways to reduce the weight of the old-style Cornish pumping engines, which is not at all surprising when we consider the huge weights which are kept almost constantly in motion in order to effect the drainage of mines, the moving parts weighing all the way from 50 to 400 tons. In the direct single-acting Cornish engine there is not the same objection to this enormous weight as there is in the rotary engine, as the inertia of the rod and engine on the change of the down to the up-stroke is effected without loss of power by the compression of the steam between the piston and the cylinder end, the compressed steam being utilized to overcome the inertia at the commencement of the up-stroke, which accounts in a very great measure for its superiority in point of economy over the old-style rotary engine, although inferior to the modern rotary pumping engine.

It is evident enough that the loss of power in reversing the motion from the down to the up-stroke in the rotary engine, when running fast especially, is very considerable, and that the greater the weight of the machinery in motion the greater is the loss of power, and it has appeared to me for several years that there was a good opportunity for some one to reduce what in this enlightened age appears, to mine owners especially, the outrageous weight of these engines, and especially so where freight and fuel is high, and I have no doubt it will be interesting to every one engaged in mining operations to learn that I have succeeded in reducing it seventy per cent, and instead of a rod, weighing, say 150 tons, traveling at the rate of two miles an hour, my rod is only forty-five tons weight to do the same work, and, besides, requires no balance bobs in the shaft, which is alone an immense saving; some of the deep mines using three or four, for which large, expensive excavations have to be made in the side of the shaft, in addition to the cost of the bobs.

In order to overcome the inertia of this reduced weight, I have adopted a spring buffer similar in action to the steam buffer above mentioned in the Cornish engine, which takes effect in my rotary pumping engine just as it approaches the end of the down-stroke, whereby the effort to stop the rod at the end of the down-stroke is done by the spring instead of by the engine, and the spring relaxing as soon as the crank turns center exerts itself to overcome the inertia at the start of the up-stroke by which this loss of power is almost entirely overcome. This will appear all the more important when you consider it is repeated 20,000 times in twenty-four hours when the engine is going full speed. The buffer or buffers consist of a large area of vulcanite, and is adjusted by screws when in motion, and causes no jar whatever on the engine with a small fly-wheel on the crank-shaft. This engine is so constructed that it can be driven by electric power as well as with water or steam power, provision being made to allow the electric machinery to get into motion before the pumps are set in motion by means of a brake clutch, which dispenses with the difficulty hitherto experienced in starting the heavier kind of machinery with electric power.

This great reduction in the weight of the machinery is accomplished simply by adopting double-acting instead of single-acting pumps, and by an important modification in the construction of the rod. In the double-acting pump the column of water is only one-half the weight and size it would be if a single-acting pump was used, evidently, and hence a great relief to the valves and foundations of the pumps, and the rod of course only requires to be heavy enough to force the columns on the down-stroke and strong enough to lift them on the up-stroke. This extra strength is acquired by constructing the rod in the usual way, excepting that it is only one-third the weight, and two steel plates extend its whole length, so that I am not relying on the tensile strength of the wood but on the steel plates, which are twenty times stronger than wood, the latter being used only to give rigidity and weight to the rod, and thus avoiding the ordinary risk of breaking the wood rod, which has been a curse to mining from its infancy.

I use both a double-pole plunger pump with self-lubricating stuffing boxes and a double-acting piston plunger pump, provided with a self-lubricating piston and self-lubricating stuffing box. They are both provided with self-tightening stuffing boxes when they are liable to be submerged for any length of time. These stuffing boxes are also provided with bolts for tightening them in the usual way, which I hope will remove the prejudice existing in some quarters against the automatic gear. The plungers and the piston rod are guided in the centers of the stuffing boxes the same as the piston rod of a steam engine, and to compensate for the swelling of the ground and wood the guides are adjustable by screws, thus avoiding the cramping in the stuffing box attending the old style of wood guides without proper means of adjustment.

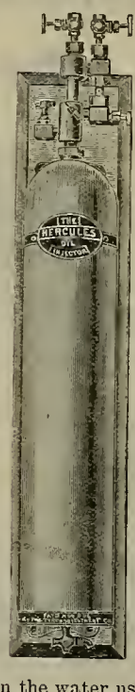
One would have thought that this great reduction in the weight, combined with a general improved condition all round, while retaining the valuable and generally approved features of the Cornish type, would have been sufficient to satisfy every one, for the time at least; but this is very far from being the case. Attempts are being made to do away with transmission rod and motor on the surface both by electricity and compressed air derived from water power a great distance from the mines. Well, I have been mining all my life, and every attempt at dealing with large quantities of water with machinery down the mine has almost invariably resulted in its being sooner or later drowned, while with the Cornish system, however often the mine may fill with water, it will pump it out again.

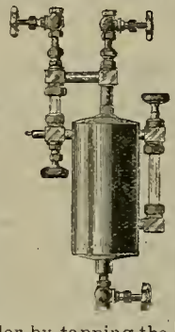
The greatest difficulty in mining is to keep the bottom of the shaft dry, so that you can sink, even with the most reliable machinery. It is obvious enough, I think, even to those who have never been down a mine, that every time the pump stops the water accumulates in the bottom of the mine, and no more sinking can be done until it is removed, and that if there are repeated stoppages very little or no sinking will be done; and the same thing retards all the operations in the bottom of the mine. In fact, the effective drainage of a mine is the life and soul of it, because it does not matter how rich the ledge may be, you cannot work it under water; and although I am a great admirer of electricity, I think it less adapted to the drainage of mines than any other purpose on account of the multiplicity and distribution of its parts when derived from water power a great distance from the mine. WM. NANCE.

Grass Valley, Cal.

Hercules Boiler Oil Injector.

The use of kerosene oil in boilers has heretofore been somewhat retarded by the inability to secure some device that would insure its entry into the boiler in quantities sufficiently minute to produce satisfactory result. The Hercules Boiler Oil Injector, herewith illustrated, feeds by the drop. It is easily attached to the feed water pipe anywhere between the pump or injector and boiler by tapping the feed water pipe and screwing in two one-fourth inch pipes, which are brought down to and connected with globe valves on machine. The injector must always be below the feed water pipe. These connections can be made between the pump and heater, if desired, and have the oil pass through heater, and also keep that free from incrustation. This is especially desirable with many kinds of heaters, as they are liable to get stopped up by scale. The injector is entirely automatic in operation. Once set for the number of drops per minute required (according to the amount and kind of mineral matter in the water used), it requires no further attention except to refill when empty. It is for sale in this city at the machinery depot of the Parke & Lacy Co., 21 & 23 Fremont St.





Wanted to Put It in Escrow.

One day this week the mining recorder of Trail Creek district was up at Rossland. He was approached by a Spokane capitalist, who would buy a mine, or the makings of one, if he could only get a miner's license without paying for it. Said he to the mining recorder: "Can't you issue a miner's license in blank, and leave it here with my friend, who will fill in my name and send it to me at Spokane if I should have occasion to use it?" "No," replied the mining recorder; "I am not issuing miner's licenses to be placed in escrow."—Rossland Miner.

"If a fellow attacked my opinions in print, would I reply? Not I," said Oliver Wendell Holmes. "Do you think I don't understand what my friend, the professor, long ago called the hydrostatic paradox of controversy? Don't know what that means? Well, I will tell you. You know that if you had a beut tube, one arm of which was of the size of a pipestem and the other big enough to hold the ocean, water would stand at the same height in one as in the other. Controversy equalizes fools and wise men in the same way, and the fools know it."—The Outlook.

Mr. McFadden's Exaggeration.

TO THE EDITOR:—When in Sonora some two weeks since, I saw an extract in your paper from some San Francisco daily, signed by one McFadden, in which he stated that he had recently been to Folsom and tried what he could make rocking for gold. He made 60 cents the first day, and, after being shown how, made $2 and $3 a day, and said that there was room there for hundreds of the unemployed to do the same; and also mentioned that the water company charged so much for the water used. I have been looking for just such a chance through Calaveras and Tuolumne counties, and at the same time looking for work, and I was induced to make my way to Folsom by reading the above. When I arrived there I got acquainted with four placer miners who have been working all winter, and they told me they were not going to work at rocking any more, as they had only made thirty cents a day all winter. There is a large land grant here, called the Natoma grant, on which they were mining, and the Natoma Company rent out water from their ditch. So, finding out that a Mr. Silverhorn had charge of the water and would be likely to know if any one was making money at mining or not, I went and saw him. He had heard about what McFadden had said, and he immediately said it was false and could not be done, and he also told me of an old miner who was working there and could no longer make his grub. He said McFadden might have taken out what he did by cleaning up some old sluice-box or something of the kind. I understand there is one small company sluicing and making wages, while another near by are running behind. I have long thought that the days of the rocker are gone by, and only the hard times made me think of trying it, and these $2 or $3 a day diggings are not lying around loose.

Auburn, Cal., March 9, 1895. S. HORTON.

Personal.

W. G. DODD of the Union Iron Works has secured letters patent on his new ore crusher.

MR. A. F. MANNING has returned from Lewiston, Wyo., where he bought a promising mine.

A. N. PETERSON, of Sutter Creek, has been engaged as millman for a ten-stamp mill near Mokelumne Hill.

T. A. RICKARD has resigned mine management at Rico Col., and resumes his work as consulting mining engineer in Denver.

SUPT. DAGGETT of the Mint has gone to Anspi, Sonora, Mexico, where he owns a gold mine which is about to be reopened.

E. T. HARRISON has been appointed Pacific coast agent of the Hannibal & St. Joseph and associated roads, with headquarters in this city.

COL. H. R. AYRES, resident manager for Fraser & Chalmers, Chicago, has returned home from an extended trip through the west half of North America.

L. A. PELTON, of this city, has been awarded the Elliott-Cresson medal by the Franklin Institute, for his improvements in tangential water wheels.

SUPERINTENDENT SHINN of the Hayward-Lane new gold mine at Silver Bow Basin, Juneau, Alaska, expects to return in about a month, taking the new thirty-stamp mill, referred to in last week's issue, up with him.

F. VON WEISSHUHN, a Berlin scientist, recently sent by the German Government to make an examination of the mineral resources of this country, is traversing Colorado on his journey westward. He expects to make an extended sojourn in this State.

HERBERT LANG, ore buyer for the Selby Smelting and Lead Company of San Francisco, is about to remove from Seattle to Spokane, Wash. The Selby Company is an extensive buyer in that section, its business last year amounting to about $2,000.000.

W. B. STOREY JR., recently connected with the Debris Commission, has been appointed engineer of the San Francisco and San Joaquin Valley railroad. He is a graduate of the State University and is a native of California. He was for a long time assistant to the chief engineer of the Southern Pacific.

DR. S. H. EMMONS has received $5000 from the United States Government for the use of his new explosive, known as emmanite, of which he is the inventor. This is not an out-and-out purchase of his right, but merely payment for a trial of the compound, to ascertain whether its adoption by the Government is advisable. If adopted, Mr. Emmons will secure a royalty on all used.

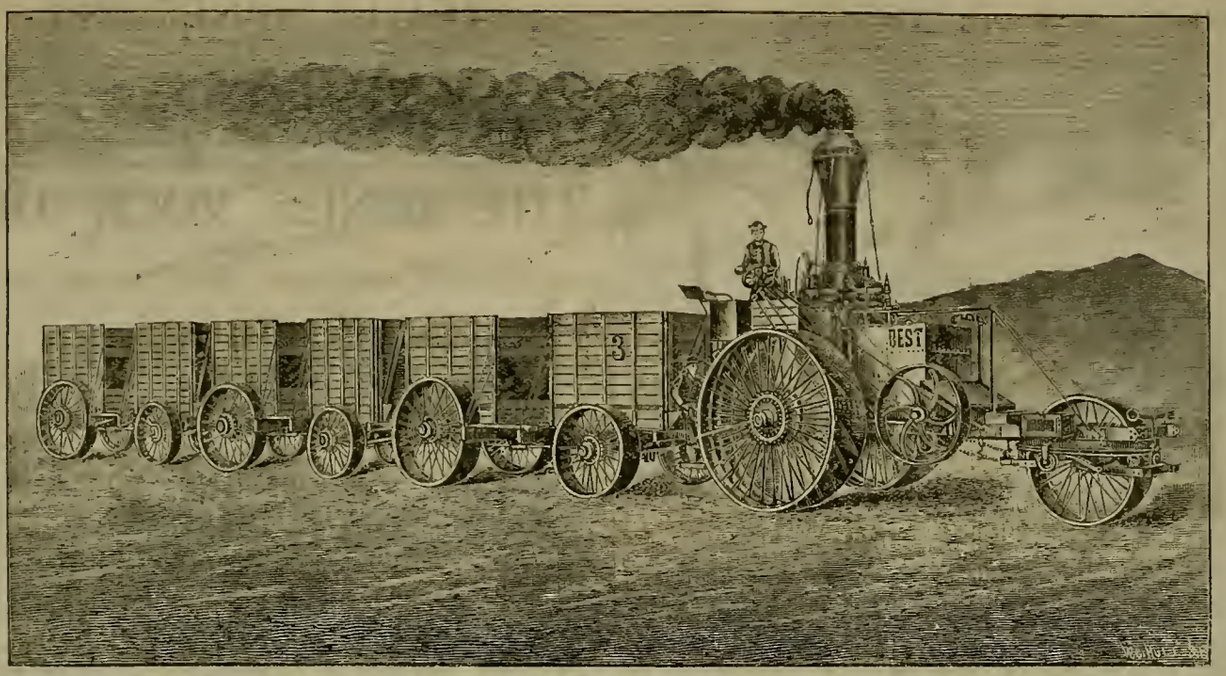
Obituary.

L. T. DAY, chief adjuster of the United States mint, died suddenly at his residence on the 12th inst., aged 46.

I. J. VAN ARSDALE, engineer of the Trihune mill at Golden, Okanogan county, Wash., was caught on a shaft in the mill last week and instantly killed.

FREDERICH E. SICKELS, aged 76 years, the inventor of the Corliss engine, died in Kansas City, Mo., on the 10th inst. from heart disease. Among his many inventions was the Sickels automatic trip steam cut-off.

AN ENOLISH PAPER contrasts the cost of a steamer of 3500 tons capacity built on the Clyde in December, 1889, with the cost at which such a boat may be purchased from the same builders at the present time. The former price was $157,500 against $107,500 at present. Machinery is the same in both cases—triple expansion, 22, 35 and 59 inches by 39 inches stroke.



STEAM FREIGHTING TRAIN.

ENGINE, 50-Horse Power. CAPACITY OF TRAIN, 50 to 65 tons; depends upon the roads.

MINING, MILLING AND SMELTING MACHINERY.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

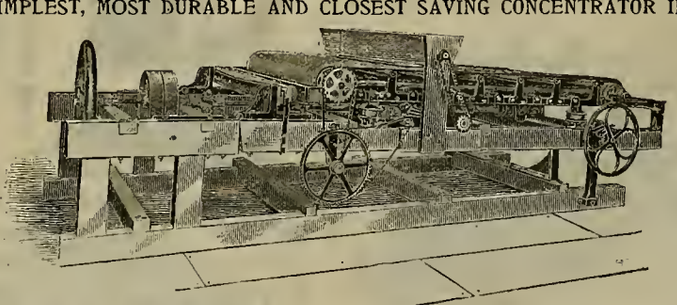
NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE McGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one third the cost in wear of any other crusher on the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

The Pelton Water Wheel Company, General Western Agents

Scientific Progress.

Formation of the Rings of Wood in Trees.

The many differences of opinion that even eminent men are presumed to hold in regard to the character of the so-called annual rings of trees, would be readily reconciled if a little thought were given to the manner in which wood is formed as the trunk is enlarged. This is accomplished by the birth of new cells, which proceed laterally from the old ones. The new course of cells take their place around the mother cells, and form a thin layer over them, just as a sheet of writing paper might be wrapped around another. These in a few days again become mother cells, and another course is produced. This continues during the short time devoted to the growth, perhaps a dozen times, and the mass of new wood known as the new annual layer is really made up of a dozen fine layers so small that the concentric lines are only visible by means of a powerful microscope. Now the size of these cells depends on the amount of material at command.

The original mother cell that starts the annual growth has had the advantage of the best opportunities for stored nutrition; every successive addition is weaker and weaker, until the last growths of the season are very small. It is because they are so small and packed close together that we can readily see where they end, and thus detect the extent of the annual layer even in old trees. Now a tree may be in a position to have command over a superior stock of nutrition, and the cells are in a condition to avail themselves of the advantages, especially if the cells are naturally of a large size, as they are in some trees. In the European silver linden, for instance, the cells are one-fourth larger than they are in the common American linden; and in this and similar trees, a number of light rings can usually be traced in the annual increment. The same can often be seen in vigorous specimens of the cottonwood.

But plainly as these lines may be seen, the experienced investigator can rarely be mistaken on the last line made during the growing season, and is able to tell how many years the tree has been growing on the spot where it stands. There is nothing more certain than that in the hand of an expert the age of a tree can be determined by its annual growths.

ACETYLENE, the most powerful illuminant of the hydrocarbons, can now be produced on a commercial scale, says Prof. Lewes, in a paper read before the Society of Arts. It is a colorless gas with an intensely penetrating smell, resembling garlic, so that the smallest leakage would be quickly detected. Five cubic feet of gas will give a light equal to 240 candles for an hour. It is made by mixing forty parts by weight of finely ground chalk or lime with twenty-four parts by weight of any form of powdered carbon in an electric furnace and adding water. The product is lime and chalcic carbide, a pound of which will yield 5.3 cubic feet of acetyline. The carbide can be made for $20 a ton; the gas would cost about $1.60 a thousand feet, but its illuminating power would make its cost about equal to coal gas at twelve cents a thousand feet.

THE *Moniteur Industriel* records the fact that on the shores of Brittany, between St. Malo and St. Lunaire, in the vicinity of the St. Enogat station, at a place called Port Blanc, the tides have lately displaced a considerable amount of sand to a depth of nine to thirteen feet. Forests which have been buried for eighteen or twenty centuries have been thus brought to light, to the great astonishment of the seafaring people of the country. A great forest has in fact been discovered in process of transformation into coal. Ferns and the trunks and barks of trees are to be seen in an advanced state of decomposition. They are already beyond the peat stage, showing the films and flakes which are found in coal. Some of the trunks are sixteen feet in length, still very distinct, although becoming quickly transformed.

SOME PEOPLE insist that when an oak forest is cut down pines spring up, and that oak follows pine, and so forth; but this never occurs except where the two kinds are not far from each other. In localities where but one kind exists that kind succeeds itself. An intelligent Nevada correspondent notes that where the pine timber was cut away twenty years or so ago, fine young trees, apparently about fifteen years old, now cover the same area. They grow so slowly when young, she says, that few observe them, but after a few years they grow rapidly. It is about the sixth or seventh year before they start on the rapid growth.

TAUGHT BY MAIL THOROUGH PRACTICAL

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.

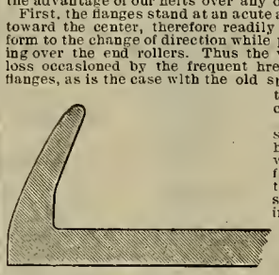
Office and Warerooms: 9 FREMONT St., San Francisco, Cal.

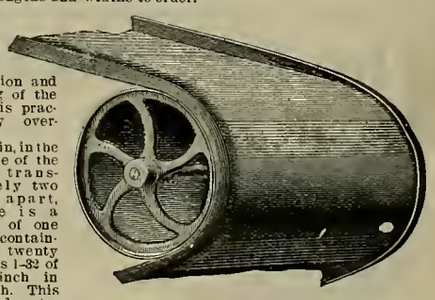
Or, Address the Company at its Denver Office.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.





Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from hanking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

Aluminum Alloy.

"The amount of misinformation on the subject of aluminum makes me sick," says Mr. Leonard Waldo, a well-known engineer, to *Machinery*. Then he told of his experiences in casting aluminum bronze. His company has poured more of the stuff down holes than any other concern in the country. He showed a section out of a propeller wheel which was to have withstood a pressure of 60,000 pounds, but didn't. The fault could not be determined. One caster thought the metal was poured too hot, and another said it was poured too cold, and a third said it wasn't poured right. The fact was, Mr. Waldo said, that the way to success must be felt with aluminum as with everything else. "When the material is what it should be, and the work is done right, this metal is the king of bronzes. There is no other known material which will give the mechanical value that aluminum bronze will. It is possible to give it a strength of from 900 to 100,000 pounds to the square inch. "But," said Mr. Waldo, "I must put on record a protest against an alloy called aluminum alloy. With reference to this controversy as to whether it should be called aluminium or "aluminum," continued Mr. Waldo, "I will tell you what happened to me. I had the misfortune to deliver a lecture on the subject of this new metal. Right in front of me sat a bright boy of about high-school age, and his mother. Evidently they had had a dispute as to the proper word. As I proceeded I had occasion to refer to Sir Humphrey Davy, and, of course, I said aluminium. I saw the lady turn to the boy and smile. His face fell, as if he had met a bitter defeat. A little further on I used the word again, and this time, remembering that the directors of my company had, by a solemn vote, decided to call it aluminum, I called it aluminum. Now it was the boy's turn; he grinned and nudged his mother with evident satisfaction. In England it is aluminium. In America, by the act of the corporation which handles it, it is aluminum. I don't know how we shall decide the question except to leave it to popular taste."

An engineer remarks in an exchange that the grate bars under his boiler became warped and overheated, and consequently soon wore out. The steam requirements were very irregular, and the fireman, when demand ceased, opened the fire doors to keep the boilers from blowing off. This cut off the cooling draft through the bars, and the burning bed of coals superheated them. The difficulty was obviated by making a steam connection with other boilers used for other work, and allowing the fires to burn low at full dampers.

"What Is a Machine?"

The question, "What is a *machine?*" is not so abstruse as the question involved in the consideration of "What is a process?" Every one knows what a machine is. In the common acceptation of the term it is a device composed of one or more parts for performing mechanically certain operations. As to whether the machine is new or not, or sufficiently novel to render it patentable over the prior art, is the important question involved in most cases in which the machine constructions are concerned. Patents are constantly granted for *improvements* upon machines in their minutest details, provided the improvement is novel and useful and is capable of the exercise of the inventive faculties. The word machine, in the patent law sense, is broader than in the ordinary acceptation of the term.—Machinery.

Important If True.

A Springfield (O.) dispatch reports the invention by George Harley, a foundryman, of a process for making malleable iron of excellent quality direct from molds. A company has been incorporated with $1,000,000 capital. By Harley's process iron is made from an endless furnace with a peculiar method of controlling the admission of air, by which a thoroughly molten condition of iron is obtained. It is said that Bethlehem (Pa.) iron men have expressed a willingness to give $10,000,000 for the invention on proof that it is what it is claimed to be.

Yellow sheet brass scrap usually contains from forty to sixty per cent of zinc and lead. It does not, therefore, have a great amount of copper in it, and should not be used in bearings of any kind where a wearing surface is required.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

CHARLESTON DISTRICT.—*Record:* The old Acme mine may shortly start up. It was worked successfully twenty years ago. A hoisting engine and ten-stamp mill are on the property. It is thought that the company now taking hold of this mine will be rewarded for the money expended in opening it, providing the money and labor is economically used. The mine showed good indications of paying well when it was shut down in 1882. There are three different chutes of ore which are of high grade, and between each distinct chute is a mass of low-grade ore. The chutes dip away from the working shaft at an angle of about forty-five degrees, making it necessary for them to run through barren ground for a number of feet before reaching the pay ore. The last work done by the company was the sinking of one hundred feet and then cross-cutting a few hundred feet, and still driving the tunnel ahead. Then a difficulty arose between the superintendent and one of the engineers, which resulted in the wounding of the engineer by a shot fired by the superintendent. The latter was tried on a charge of attempt to commit murder, and the mine was shut down just as everything was ready to take out ore, all the dead work having been done.

The Excelsior mine is still working to its full capacity, the five-stamp mill being kept going night and day.

The Iron Mass mine, owned by A. A. Cline, is prospecting well. This is a new location recently discovered.

The Champion mine, owned by Messrs. Deneud and Linton, is reported as looking well. They have just put up a horse whim and sunk the shaft about fifty feet. They intend sinking fifty feet deeper before running the levels and stoping out the ore.

ONEIDA.—This mine has been idle for the last fifteen years. James D. Hague has been asked by Seligman Bros., of New York, to make a thorough investigation of the property. In face of the bonanza developments of the Kennedy on the south, and the promise of a good paying mine in the South Eureka on the north, it is the impression that he will recommend the starting up of the property.

THE ANITA — JACKSON DISTRICT. — *Ledger:* Sinking in the Anita mine is suspended, preparatory to putting in a steam pump.

ALPINE—PLYMOUTH DISTRICT.—Wm. Hooper has taken fifty tons of rock out of the Alpine mine, from near the surface, and will make a mill test of it at the Ivanhoe mill.

ALLISON—PLYMOUTH DISTRICT.—The Stockton people who have been mining in the Allison, have a shaft down fifty feet and have struck a rich chute of ore at about fifty feet.

MAHONEY—SUTTER CREEK.—Water is down at the Mahoney shaft about 750 feet. When the 800 level is reached Superintendent Ross will commence to drift south to strike the north drift from the 600 at the Wildman, to connect the two mines. Work has already been commenced on repairs at the Mahoney forty-stamp mill.

THE GWIN MINE.—The three-compartment shaft at the Gwin mine is some 600 feet deep and in hard gray rock, with but little water in the mine. They are sinking an average of fifty feet a week. About twenty men in all are employed.

BAY STATE — PLYMOUTH DISTRICT. — C. D. Lane and Hayward of the Utica have proposed to the owners of the Bay State mine that if given one-half of the stock of the company they will pay the debt of the property, put on ten more stamps and conduct the property without further assessment to the stockholders. The Plymouth stockholders do not take kindly to the proposition, as there seems to be no guarantee as to the length of time the property will be conducted by the Utica people.

THE ALMA—JACKSON DISTRICT. — The new hoist at the Alma works well.

THE LUCILE—PLYMOUTH DISTRICT. — Work was practically suspended about a week on account of foul air encountered as the water was lowered in the shaft and taken from the old works. A blower has been put in, pipes connected and work resumed. The water is down in the shaft about 400 feet.

Calaveras.

NOT SOLD.—*Echo:* Some time since we published (upon what we supposed to be good authority) that the Blair mine, near Smith's Flat, had been sold for a large sum of money. We have since learned that such is not the fact, and that the mine is still in the hands of the original owners.

TO FURNISH POWER.—A company is organizing in Chicago to install a large electrical power plant on the Stanislaus river, to furnish power for mining purposes in Angels Camp and vicinity. The company having the Angels mine in charge are instrumental in its organization.

MILL STARTED.—The mill at the Linderaxa mine was started this week. Work in the mine is progressing and ore is being extracted.

AN INCORRECT REPORT.—The report that the Debris Commissioners stopped the Central Hill Mining Company from mining is denied. The mine is reported in full swing, and will so continue.

THE BEATRICE MILL.—The Beatrice mill is running on quartz from the Oro Plata mine from the Hill shaft. The concentrates from the Beatrice mine are run through the mill again and over the concentrators preparatory to shipment. The mill is fitted up with all the latest improvements and has an electric light plant.

WATER GULCH MINE BONDED.—The Water Gulch mine, owned by Zwinge Bros., has been bonded to the company that bought the Leonard mine. Men are sinking a shaft and clearing ground for the buildings that are to be erected on Murray creek.

AROUND COPPEROPOLIS.—A gold strike near Copperopolis this week has started a good many prospecting in that section.

Kern.

RED ROCK MINING DISTRICT.—In 1859-60 hundreds of placer miners were rushing into what is now Kern county. This was the great southern rush. Following the placer miners came a set of bonanza quartz miners. These men built mills right and left, some on three and four-inch stringers of quartz and all on undeveloped veins.

As a natural result, with the exception of two mines—the St. John, 720 feet deep, and the Piute Mountain mine, 300 feet deep—that happened to be very rich from the grass roots down, the tide began to turn to some new strike.

Following these $10-per-day men came a set of $10-per-month men. One by one the mills were destroyed and the mines gutted out, as far as the ore could be got at without using timbers or powder.

Sageland, once a prosperous town of several hundred inhabitants, to-day has not one board standing—nothing to show that there had ever been a town there except a few cellars and the ruins of her three mills. Such was the history of the old Sageland mining district from 1866 to 1894.

In 1894 the discovery of placer gold was made at Red Rock on the Mojave desert, fifteen miles east of the old town of Sageland. With the rush to the placer mines came the quartz prospectors, who, finding no quartz mines in the placer field, turned their attention to the old Sageland district. One by one the old abandoned mines were opened up, and in nearly every instance the ledge had temporarily pinched or had run down in value to from $8 to $15 ore.

The former owners in 1860-66 had to haul supplies overland from San Pedro, 170 miles, and this, together with the lack of experience in quartz mining and poor machinery, made their enterprise unprofitable.

But to-day, with thirty-five years' experience and improved machinery, with cheap supplies, and with labor at the present rates per day, mining should pay well. As depth is attained, and the ground thoroughly explored, in all probability ore as rich as any of the surface will be found. Recently the prospectors have opened up over thirty promising claims, most of them new discoveries. The prospectors seldom have money enough to develop their finds, and therefore have to depend on outside capital for means to work their claims, and, as a general rule, they sell out for what they can get or abandon their claims undeveloped, saddle their burros and wander on, ever looking for "a poor man's mine"—that is, a mine rich enough to make expenses with a hand mortar or horse arrastra. These veins are fissures in granite and kindred rocks. They run from two inches to several feet in width, with wood and water reasonably near for milling purposes—all free-milling ore.

We, the prospectors, have done our part, and with this letter hang out our shingle, "Capital wanted."

The McMasters-McEwen Company have a group of ten old claims in Kelso valley. They have cleaned out the old tunnels and, in many instances, opened up new works. They estimate to have several thousand tons of from $10 to $20 ore in sight, and are making preparations to put in a mill by April.

Frank Hale has a force of men at work cleaning out the old Esperanza mine, an old-time producer and formerly one of the best mines in the district.

D. L. Applegate has leased his Gold Hill mine. It will be worked by water arrastras.

The Shoemaker mine, on Shoemaker mountain, shows a clean vein of from one to three feet, from which 112 samples, reduced down, assayed $14.47 per ton.

Mr. Moore, on Pinte mountain, has his twenty-seven-foot water arrastra finished, and will soon begin crushing. He has two claims, one of about eighteen inches and one of six feet, of $8 and $10 ore.

THE BUTTERBREAD SPRINGS GROUP.—Butterbread Springs is on the desert side and has plenty of water, but all timber will have to be hauled twelve miles. There are about fifteen promising locations within three miles of the springs.

The Mexican mine—R. N. Binford, owner—has closed down. I hear he refused $15,000 the other day for the mine, from San Francisco parties.

J. Artez and several others have uncovered a vein of from two to four feet, which assays $30 to $75 per ton.

Messrs. Howe and Rice will soon thoroughly prospect the Padre and Sixty-four mines.

The pioneer claim of the camp, the San Juan—J. Whitrock, owner—shows eight feet of ore that assays from $9 to $47. This claim is lying idle.

Mr. Benson's North Star shows four feet of low-grade ore. There are several claims joining the San Juan and North Star, but not enough work has been done on them to determine their value.

Near the Sixteen-mile House is the Harrelson ledge that averages sixty feet and assays $2.70 across the vein. This is the last claim on the mineral belt, and it is where the desert and mountains meet.

Mariposa.

DISTRICT ABOLISHED.—The miners of the Coulterville district have abolished that district, stating that the Quartzburg mining district was formed on June 25, 1851; on March 5, 1864, the Coulterville district was created from a portion of the Quartzburg district; the laws of the United States superseded the old regulations, making the district system obsolete and unnecessary; that no election for officers of the district had been held for years, and that the holders of claims had long disregarded the local district laws.

THE HITE MINE SOLD.—The Hite gold mine, twenty miles from Mariposa, has been bought for San Francisco and New York capitalists, for $100,000. It has a forty-stamp mill and free water power. On the 1st of next month a force of men will go to work.

Nevada.

QUARTZ MINING NEAR COLUMBIA HILL.—*Herald:* A good ledge of fine quartz has been struck in the claim adjoining the Grizzly Ridge mine, not far from Columbia Hill. Considerable prospecting has been done and the owners are satisfied that they have a good mine. All that is needed is to properly develop it.

The Live Oak mine, in the same vicinity, is looking well and some fine quartz is being taken out. The quartz-mining outlook is very promising in that section, and it is believed that there will be unusual activity there this summer.

Placer.

OPHIR.—The Gold Blossom at Ophir has made a strike. A body of galena sulphurets and gray copper has been struck in the east 180-foot level. Assays show the ore to be valuable.

THE North River hydraulic mine at Yankee Jim's is now running.

San Diego.

PADLOCK MINE.—Potter brothers and Cook, who recently purchased the Padlock mine at Julian, are hard at work developing their property and feel much encouraged over their prospects, says the *Sentinel*. They have opened up a good-sized ledge and are pretty confident there is money in sight for them. They have granted two leases on different parts of the mine, at which work will begin right away.

Sacramento.

AT FOLSOM.—The *Telegraph* says: "The McCue-Bates mine is now running in full blast and a large force of men is at present employed there, most of them working overtime. They are down about 100 feet—way below bedrock—where it is said that gold has been struck in such quantities as to be easily discernible among the gravel with the naked eye. The owners, and the community of Folsom generally, are well pleased with the outlook there, which no doubt will be a valuable acquisition to our town."

Sierra.

BALD MOUNTAIN.—The Bald Mountain Extension mine, at Forest City, has resumed operations, employing fifty men.

Trinity.

JUNCTION CITY PAYING PROPERTIES.—*Journal:* The Lorenz-Leihbrandt group of mines on Red Hill are showing well. On the 1st of this month a partial cleanup, the first of the year, yielded $6300, of which $3000 was a dividend to the owners, probably the first dividend from any placer mine in the county this year.

The mine is well equipped, and is supplied with all the water that can be used to advantage. Two giants are used and are running night and day. The bedrock ditch used in operating the mine is one of the deepest in the county—800 feet long, 15 feet deep at its upper end and about 140 feet deep at its outlet.

The Day & Begel mines and the Jacob Bros. mines, in that neighborhood, are also being worked.

The Hayes mine, now owned by the French Company, has a full complement of men at work, and a large amount of gravel is being moved.

Tuolumne.

EAST OF THE STANISLAUS.—Col. Dorsey, it is said, now has control of all the mines owned by him and Mr. Elliott, east of the Stanislaus river; and he is making preparations to work them. A mill is being erected. Good quartz is found in abundance on that side of the river, near the mill.

NEVADA.

ON THE COMSTOCK.—Condensed official reports say: 1650-foot level—On the sixth floor in the new ore body, at a point 125 feet north from the vertical winze which connects with the 1700 level, an east crosscut has been started and advanced 39 feet; in a quartz formation which assays from $6 to $10 per ton. On the twelfth floor the east crosscut has been advanced 40 feet; total length 65 feet; in low-grade quartz, the face being in porphyry. On the thirteenth floor, which is the fifteenth floor above the 1650 level, an opening has been made fifteen feet in length—north and south—showing ore four feet in width lying against the west wall and assaying on the average $30 per ton. From the south drift from the east crosscut from the main north lateral drift on the sill floor of this level, at a point twenty feet in from its mouth, we have stoped out to the height of fifteen feet along the west wall in ore which averages $40 per ton. 1750 level—The drift running south from the south end of the stope on the fourth floor has been extended twenty-five feet; in a porphyry and quartz formation which carries a low assay value. The ore extracted during the week came from the thirteenth floor above mentioned, and from the opening made from the south drift from the east crosscut on the sill floor of the 1650 level—amounting to 44 tons, which assayed, per mine car samples, $45.84 per ton.

Ophir—Quartz giving low assays is being cut in the openings 80 feet above the 1465-foot level. The same material is also being found in working south and upward from the 250-foot level in the old Central tunnel region, while north of the old Mexican shaft connection has been made between the winze and upraise spoken of in the last report, and quartz assaying $6 to $10 is being found.

Andes—Have cut out a station at the top of the upraise from the 420-foot level, and are preparing to start a west crosscut from the end of the south drift from the upraise at a point fifty feet up. The official letters from the other north-end mines are merely statements of the distances run while doing the usual exploratory work, and do not report any changes in the condition of these mines.

Hale & Norcross—No. 1 west crosscut on the 975-foot level has been stopped and a southeast drift started from its face, in porphyry. The south drift from No. 1 west crosscut is in 68 feet and is following a narrow streak of ore, yielding low assays. On the intermediate level, 30 feet below the 975 level, the small streak of ore in the south drift from the west crosscut continues the same as before reported. The north drift is in quartz and porphyry. During the week sixteen carloads of ore, averaging $41.60 per ton, were extracted.

Occidental Con.—The north drift from the west crosscut on the 500-foot level continues in ore of good quality, and the upraise from the end of the crosscut is showing ore of fair grade.

Alta—Northwest drift, 825-foot level, has not yet reached the footwall. The ore recently struck continues.

Sierra Nevada.—The south drift started at a point 193 feet from the mouth of the Layton tunnel is out a total distance of 198 feet; advanced 50 feet during the week; face in porphyry and quartz.

S. N., M. & U. Shaft.—The west crosscut from the Union Con., south lateral drift from the west drift, 1,520 feet west of shaft, 900 level, has been extended two feet during the week total length, 568 feet; face in a formation of clay and porphyry.

The east crosscut, No. 3, started from the Sierra Nevada north lateral drift, 600 feet north of the west drift, 1,520 feet west of shaft, on the 900 level, was advanced seventeen feet: total length, 180 feet; face in porphyry and clay.

Union Shaft.—The joint west crosscut from from the south lateral drift near the south line of the mine, 1,520 feet west of the shaft, 900-level, has been advanced twenty feet during the week; total length, 568 feet; face in a formation of clay, quartz and porphyry.

The joint east crosscut No. 3, from north lateral drift, 600 feet north of west drift, 1,520 feet west of shaft, 900-level, has been advanced seventeen feet; total length, 180 feet; face in porphyry and clay.

Challar.—The south drift on the eighth floor of the north stopes above the 550-level has been carried to a total length of fifty-one feet; advanced during the week fourteen feet; face in low-grade quartz assaying $8 to $15 per ton. Extracting the usual quantity of ore from the stope between the 450 and 550 levels, the yield for this week being 223 tons and 1,200 pounds, which has been shipped to the Mexican mill for reduction, the average battery sample of which was $29.28 per ton. On the 650 level the north drift has been cleaned out and repaired 130 feet during the week, or a total distance of 190 feet from the main west crosscut.

Potosi.—The south drift on the 550 level from the bottom of the 450 level winze is out fifty-four feet, thirty-two feet having been added during the week. It is following a narrow streak of ore, giving assays from $25 to $50 per ton. Have saved during the week twenty-two tons and 200 pounds of ore, car samples of which assay $35.20 per ton.

Bullion.—The west drift from the 820 level has been advanced during the week thirteen feet; total length, 1,408 feet; face in soft porphyry with a strong flow of water.

Alpha.—Have advanced the north lateral drift on the 450-foot level seventeen feet; total length, 192 feet; face in hard porphyry, with stringers of quartz through it. At a point 145 feet north of the main west drift have started a west crosscut; face in porphyry and quartz.

ALASKA.

AT SUM DUM BAY.—*News:* N. S. Trowbridge, superintendent of the Bald Eagle Mining Co. at Sum Dum bay, has commenced operations early this year, as he proposes to finish all construction work before the snow melts from the canyons and hills fronting Sanford Cove. He had eleven men with him, coming up from the Sound and San Francisco, and five others went down from here the first of the week to join the force. Among them were P. C. Plummer, John Mitchell and John Harris. He has started the men in building a mill, 30x60 feet, up the canyon about a mile from the beach, in which he will erect a four-stamp battery.

ARIZONA.

BIG SILVER STRIKE.—*Miner:* Report comes from White Hills that an immense body of ore has been encountered below the water level in the G. A. R. mine, owned by the White Hills Company. Samples from the vein run over 1100 ounces in silver and four ounces gold per ton. This is the first strike of ore that has been made below water level and proves that the mines go down.

TO BE UTILIZED.—The old El Rio ten-stamp quartz mill is being torn down to be shipped to a mine twenty miles south of Tucson. The purchasers will take the boiler, engine and stamps. The mill was put up by Childs & Gillespie of this city to work Cargo Muchaeho ore, but the venture was unprofitable owing to the expense of hauling the low grade ore to the railroad five miles. It has been idle for years.

AN UNBIASED OPINION.—E. M. Wade, a Los Angeles assayer, judges from a trip through Arizona that with more capital Arizona would be a great mining section.

Among other of the camps visited by Mr. Wade was the Washington, in the southern

part of Pima county, thirty miles from Nogales, a solid mountain of limestone cut up by veins of copper, silver and lead ores. For two miles this mass of limestone may be traced, all cut up by these interesting veins of valuable mineral. A Duquesne company began to mine, and has been succeeded by an Indiana company, and these people have put in concentrators by means of which 100 tons of ore per day are handled. Of course it is a low-grade proposition, but the supply appears inexhaustible. The assays have averaged twenty-eight ounces in silver, $3 in gold, and about eight per cent copper, with just enough zinc to make the ore somewhat refractory. One of the most promising locations is being negotiated for by Los Angeles parties, and if the purchase is consummated there will be a good return on the money invested, despite the fact that considerable money will have to be expended in a concentrating plant, in addition to which the concentrates will have to be smelted.

About forty miles southeast from Tucson, in the Santa Rita mountains, work is being carried on at the copper mines of L. J. Rose. The ore is very fine and all that has been the matter has been that it wasn't developed. As the property is opened up and the ore accumulations warrant the starting up of the $60,000 smelter erected, the outlays made will be more than recouped. At Greaterville, a small camp close by, there is some good placer ground that has yielded largely in the past, but Mexicans are now working the ground almost entirely, and there is little shipping ore being taken out by chloriders. Mr. Wade passed a month at the Glory mine, eighty miles southeast of Tueson, and which belongs to Capt. G. G. Mullens, Shirley Ward having a slight interest. The property is at present in the hands of a receiver, but the outlook is good and encouraging. A tunnel has been run in for about 400 feet, and a large body of low-grade ore uncovered which averages from $6 to $8 per ton, and which is a free milling proposition. The vein is about fifty feet in width and has a vertical dip of about sixty deg. Most of the ore in the vicinity is of a porphyritic character, but, rather strangely, in the Glory, while the formation is porphyry, the ore is mostly white quartz and exceedingly hard.

After an extensive trip through Arizona, Mr. Wade believes there would be little difficulty in getting the necessary capital for development purposes if the owners did not hold them at such extravagant figures. With a little more modesty in this direction the mining industry of Arizona would receive an impetus that would enrich the Territory.

SALE OF THE MAMMOTH.—Tombstone *Prospector:* Col. Zabriskie, of Tueson, who has about concluded, with his associate in New York, a sale of the Mammoth gold properties, returned a few days since from the East. The sale which is about to take place includes the Mammoth as well as the Collins group, at Mammoth.

THE COPPER GLANCE.—*Prospector:* The machinery for the Copper Glance Mining Co. has nearly all arrived, and is being hauled to the mine and put in running order as rapidly as possible. A new force of men is to be employed, and the output of ore to be increased. The ore runs very high in silver and is 35 per cent copper.

MONTANA.

THE DRUM LUMMON MINE.—*Reporter:* R. T. Bayliss, superintendent and managing director of the Montana Mining Company, or the Drum Lummon mine, was recently in London, where he presented a circular letter to the stockholders explaining why the sixty-stamp mill stopped work last February. The mill was erected specially for the treatment of low-grade ores. It was decided that in order to keep this mill in operation it would be necessary to employ six additional machine drills in the extraction of ore from various parts of the mine. The mill, however, will remain closed down until they have accumulated enough low-grade ore to keep it in constant operation. The adoption of this policy will not affect the regular monthly profit now being earned at the mine, as the grade of ore treated in the fifty-stamp mill will be of higher value, and the directors are advised that this arrangement is fully justified by the accumulation and increased value of the high grade ore developed during the past year.

NEW MEXICO.

A RICH STRIKE.—A rich strike is reported in the Lone Star mine, Cochiti district; eleven feet of paying ore has been encountered. From ten assays the rock averaged $50 in gold to the ton. Bland is the principal town of the district.

OREGON.

Josephine Co.

PLACER MINE SOLD.—T. H. Donovan has sold the Philips placer mine on Jump-Off-Joe district to Judge Smith of Portland. Pipe will be purchased and work begun at once.

SOUTH DAKOTA.

HOLY TERROR CLEAN-UP.—*Pioneer:* On Tuesday a clean-up was made from the company's ten-stamp mill which netted $8000. This is from a five days' run on ore from the shaft. Yesterday a lump of rock weighing sixty pounds was taken from the mine, pounded up and panned, resulting in a one thousand dollar clean up. The rock from which this result was obtained was taken out of a drift run from the one hundred-foot level. The owners have a bonanza, as it is reported that there is rich ore enough in sight to run the stamp mill continuously for ninety days.

UTAH.

SAN JUAN PLACERS.—Great placer mining activity is reported along the San Juan. Many miners are coming in and are making good wages with the crudest appliances. Water wheels suspended between boats, such as George Goss is putting in at the Good Hope bar on the Colorado, are being successfully operated. At a point eighty miles below Bluff the gravel is being transported some distance on pack animals and worked at a good profit.

MICA MINES.—Messrs. Rogers of Asotin and Lewiston have given a deed in escrow to Messrs. Hallett and Morrison for their mica mining claims in the Robinson mining district in Latah county. Work will be commenced at once.

THE IBEX IMPROVING.—*Tribune:* The members of the Ibex Mining & Smelting Company are feeling very jubilant over the recent developments at the mine. The ore bodies are said to be constantly improving, both in extent and value. A noteworthy feature is that the copper values are diminishing, and the gold values increasing. It is reported that a hanging wall has been encountered at a depth of 175 feet, indicting the mine to be a fissure vein instead of a number of chutes.

WASHINGTON.

MINING IN THE STATE.—The oldest gold mining district in Washington and the one from which most of that precious metal has been taken is the Swauk district in Kittitas county. From 75 to 100 miners have been actively engaged in taking out placer gold since 1873. They have shown disposition to keep from public knowledge of the amount, and they have worked in a crude way with pick and shovel, but some definite figures are now accessible.

The miners are protesting against the Northern Pacific Railroad Company's getting patents to lands in the district, and last week L. H. Jansen of Tacoma, manager of the Swauk Bedrock Flume Company, was in camp making out protests and affidavits of some of the miners as to the quantity of gold they have taken out of their claims.

John Black, in twelve years	$21,000
Thos. F. Meagher, it thirteen years	20,750
C. E. H. Bigney, in two years	12,500
T. Tweet, in three years	8,000
A. W. Johnson, in three years	8,000
C. A. Deilig, in one year	2,350
Total for the six men named	$72,600

Others have taken out quantities graduating down to $150 a year.

In talking of these figures, Mr. Jansen said: "During the three years I have been acquainted with the camp, I believe large sums in gold have been taken out by both American and Chinese miners of which I took no account and had no knowledge.

"The Swauk creek camp is reached by a six hours' trip from Seattle to Ellensburg with a journey of four hours by stage from that town. The creek and its tributaries are being worked for some nine or ten miles, but only in a crude way. We have the same kind of gravel as was taken from the blue gravel diggings in California and have the old blue gravel channel; I have myself brought out several thousand dollars of gold nuggets from the camp, among them some very large ones. All the work is sluicing except one hydraulic plant, but the flume company is preparing to work it systematically on a large scale.

"The company has secured six miles of the land along the line of the creek and has contracts on two miles more. It will build a flume four feet wide and thirty inches deep from the mouth of the creek up and will hydraulic the gravel with water from reservoirs and lateral streams with 250 to 300 feet pressure, and gradually extend the flume up the stream as the ground is washed out. There is no danger of damage to farms along the Yakima river at the mouth of the creek, as the river runs through canyons giving abundance of dump and the mines can be worked nine months in the year.

"Other streams parallel with Swauk creek are also being worked and all its tributaries have been well prospected. Williams creek has some of the finest miners in the State, and an old river channel runs up it. Boulder creek has some fine prospects, but has not been worked much. There are good quartz lodges in the vicinity, in fact you can see the quartz sticking to the gold, and prospecting is going on all through the neighboring mountains, but the men are too much in the slides, where the ledges have been broken up. Very little development has been done, for the parties in there have not the means. Still several quartz mines are being worked with arrastras, and one owned by Tweet & Johnson has paid $16,000 in a sixty-foot tunnel in the last three years."

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from A. Blair, in the American House Mine, near La Porte, Plumas Co., Cal., to impound tailings behind dams in the American House Ravine; from Jay E. Russell, in the Spring Tunnel and Spring Canyon Mines, near Mount Gregory, El Dorado Co., Cal., to impound tailings behind brush dams in Spring Canyon; from Porter Phillips, in the Mount Gregory Gold Mine, near Georgetown, El Dorado Co., Cal., to impound tailings behind brush and log dams in a ravine below the mine; from Wulff Bros., in the Deer Valley Mine, near Green Valley, El Dorado Co., Cal., to impound tailings in an old hydraulic pit; from John Enos, in the Strawberry Placer Mine, near Vallicita, Calaveras Co., Cal., to impound tailings behind rock dam in a gulch below the mine; from Geo. R. Evans et al., in the Red Hill and Telegraph Hill Mines, near Rancheria, Amador Co., Cal., to impound tailings behind log dam in Chill Gulch; and from Moy Jin Mun, in the Grizzly Hill Mine, near Volcano, Amador Co., Cal., to impound tailings behind brush dam in a ravine below the mine, gives notice that a meeting will be held at Room No. 12, Flood Building, San Francisco, Cal., on March 18th, 1895, at 1:30 P. M.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Geo. W. Edwards, in the Blacklock Mine, near Placerville, El Dorado Co., Cal., to impound tailings behind a brush dam in Spanish Ravine; from Kelly & Matherly, on Rattlesnake Bar, near Auburn, Placer Co., Cal., to deposit tailings on bank of American River; from O. M. Henry, in the Dry Gulch Mine, near Volcano, Amador Co., Cal., to deposit tailings behind a dam below the mine; from J. K. Williams, in the Saw Mill Flat Mine, near Whiskytown, Shasta Co., Cal., to deposit tailings in an old hydraulic pit; and from Thomas Ewing, in the Mooney Placer mine, near Placerville, El Dorado Co., Cal., to deposit tailings in old hydraulic pit, gives notice that a meeting will be held at Room No. 12, Flood Building, San Francisco, Cal., on April 1st, 1895, at 1:30 P. M.

PICKTHALL'S
Celebrated Boiler Compound
—FOR—
Removing or Preventing Scale, Corrosion and Pitting in Steam Boilers.
Will save its cost in fuel, boiler repairs or labor.

Vulcanized Fiber Valves
—AND—
Ordinary Rubber Valves,
For Hot or Cold Water.
Pure Rubber Air Pump Valves.

COMBINED RING PACKING
For Piston Rods, Steam, Water or Ammonia.

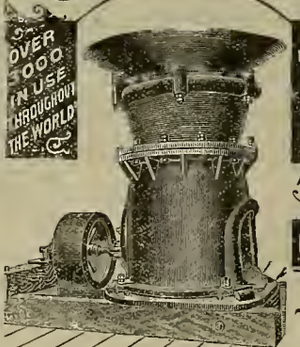
Attention Miners!

W. W. MONTAGUE & CO.
—ARE MANUFACTURERS OF—
Riveted Iron and Steel
Water Pipe
For Hydraulic Mining, Mills and Power Plants.
IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.
309 to 317 Market Street, San Francisco.

Mining Pipe!

STEEL OR IRON.—We make pipe of either, but recommend STEEL, it being superior to iron in many particulars and inferior in none.
COATING.—We use great care in COATING our pipe with a HOT solution of Double Refined Asphaltum and Maltha.
COMPETITORS.—Our competitors say we have the best appointed Pipe Shop on the Coast.
SCHAW, INGRAM, BATCHER & CO., Hardware Merchants,
SACRAMENTO, CAL.

GATES ROCK AND ORE BREAKER



PRODUCES A MORE PERFECT CUBIFORM MATERIAL AND A GREATER QUANTITY IN A GIVEN TIME PER HORSE POWER USED THAN ANY OTHER CRUSHER ON EARTH.
CAPACITIES UP TO 150 TONS PER HOUR. NINE DIFFERENT SIZES.
WE HAVE BUILT THE LARGEST STONE CRUSHING PLANTS IN EXISTENCE
GENERAL MINING MACHINERY
OF EVERY DESCRIPTION.
TREMAIN STEAM STAMPS
Connorsville Blowers, King-Darragh Concentrators, Stamps, Hoists, Rolls, Pans, Settlers, Smelters, Metallurgical Appliances, Etc.
COMPLETE INSTALLATIONS.
Investigate our late Specialties and Improvements in this class of Machinery.
GATES IRON WORKS Dept. "M," 50 S. Clinton St. CHICAGO, ILLS., U.S.A.
NEW YORK, 136 LIBERTY ST. | LONDON, E. C., 73 A QUEEN VICTORIA ST. | BUTTE, MONTANA. | CITY OF MEXICO, 8 CALLE DE GANTE.

VAN DUZEN STEAM JET PUMPS
THE BEST IN THE WORLD.
Pumps any kind of Liquid. Always in order. Never clogs nor freezes. Fully Guaranteed. COST $7 AND UPWARD. Especially useful for Mines, Quarries, Pits, Wells, Clay Pits, Breweries, on Steamships, Ferryboats or any place where steam is available and liquid to be pumped. A full supply in stock. Address,
Jas. Linforth, 37 Market St., San Francisco.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant: 164 pages, octavo. Illustrated by twelve lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Dr. Carl Barus to show tbat the molecular structure of iron can and does change under different physical conditions and at atmospheric temperatures.

A number of cases are also cited by Mr. Argall and others of broken stamp stems and other iron bars which undoubtedly show crystallization, but in this connection it may be noted that the point of discussion is not "do the fractures show crystallization?" which is disputed by no one, but "is such a structure due to continued vibration and not inherent in the iron or merely due to to the method of rupture?"

Upon the negative side of the discussion are Dr. R. Raymond, Mr. H. M. Horn, Prof. A. Ledebur, Mr. M. Osmond and others, some of whom state positively that vibration does not produce crystallization, while others simply hold that the present evidence does not prove the positive proposition.

Dr. John Percy said many years ago:

"I have not met with any evidence to justify an affirmative answer, as to whether vibration, caused by impact or otherwise, may induce a crystalline arrangement, which did not previously exist, or was only imperfectly developed."

Prof. A. Ledebur (Handbuch der eisen hutten kunde, part III, 1894) says: "The opinion that a fracture caused by repeated strains is the result of a change in structure, and particularly that fibrous wrought iron is transformed into grannlar under continuous shocks, has proved to be entirely erroneous."

Numerous experiments instituted by Badchinger, in Munich, in which bars of iron and steel were submitted to repeated shocks, led him to the conclusion that "strains of iron and steel repeated frequently millions of times bring about no change of structure."

Two very suggestive experiments are cited by Messrs. Ledoux & Durfee, by which a bar of wrought iron may be made to show in two fractures only a few inches apart two distinct sources of fracture, the one sharply crystalline, the other fibrous, dependent simply upon whether breaking force has been a sharp blow or a slowly applied load.

In the *Iron Age* of July 15th. and September 27th, 1894, Mr. Kreuzpointner, of Altoona, Pa., sums up the present status of knowledge on the subject, as drawn from his own investigations and a study of the leading authorities, both American and foreign:

1.—Crystalline appearance on the fracture is caused by the manner of breaking, i. e., transversly broken fibres show granular crystalline faces, but when pulled apart longitudinally, the same iron will show a fibrous structure.

2.—The iron in a bar may be crystalline at one point, but fibrous at another.

3.—Iron may have been crystalline at the point tested, but assume a fibrous appearance at the tensile fracture, due to the flow of metals.

4.—Changes in the component elements of iron are necessary for changes in its crystallization, and these changes cannot occur at low temperatures.

5.—Repeated stresses cannot produce caystallization.

Wohler & Spangenburg agree that alternate and intermittent stresses tend to deteriorate and fatigue metals.

Mr. Howe sums up as follows:

"Repetitious of stress, wholly unaccompanied by shock and vibration, are well known to induce some kind of deterioration, which eventually breaks iron. Vibration and shock, unaccompanied by great stress, or at least by prolonged repetition of considerable stress, has never, so far as I know, been known to break it. Examination of the fragments of pieces thus broken by repeated stress, even when accompanied by vibration and shock, has indicated that the injury was local, and careful microscopic examination of the fragments close to the fracture has detected no crystalline change, but at most a shattering and incipient separation of the pre-existing crystals, particles or grains, or whatever you may call them."

Mr. F. Osmond, a French authority on iron and steel, says: "I know of no fact which demonstrates the crystallization of iron by vibration; and all that I do know is opposed to that opinion The aspect of the fracture depends upon the original quality of the iron and the mode of rupture."

Dr. Raymond proposes that the following series of tests be made, which go far to satisfactorily settle many of the points now in dispute:

1.—Examine a stamp stem, which has been running a long time without breaking, for fracture and structure.

2.—Compare such a stem with one made at the same time from the same metal, but never used.

3.—Examine a broken stem at other points than the point of fracture.

4.—Test such a stem at any point in it and see if it is not possible to produce at will either granular or fibrous structure by simply varying the mode of fracture.

5.—Test any stamp stem, new or old, as in 4, and see if the metal acts differently from other metals.

By an act of Congress, approved Dec. 13, 1894, all land warrants, Surveyor-General's scrip issued under the act of June 2, 1858, is receivable, without fees, at any U. S. land office at the rate of $1.25 per acre, in payment for commuted homesteads. desert entries, timber and stone entries, and timber-culture entries, and land purchased at public auction, unless the land was purchased from an Indian tribe within ten years.

Consumption of Wood on the Comstock.

William Alvord. of this city, prepared a paper on the consumption of timber and wood in those mines for the meeting of the American Forestry Association in 1891, but the paper has never been published in its entirety. Some extracts from the paper are herewith given, it being observed that the statements are applicable to the date when the article was written.

The walls, ore bodies, and, generally speaking, the entire formation of this lode, are remarkable for want of firmness and tenacity. The friable nature of the ore, which renders its mining comparatively easy without blasting, except to fracture large masses, has a counter disadvantage in requiring an expensive and complete system of timbering in order to make its extraction safe. Again, some of the mines of this lode are. or have been, operated at a depth considerably exceeding 3000 feet. However, the chief reason for using large quantities of timber is the great width of veins carrying high-grade ore. On the 1550 level of the Consolidated Virginia mine a vein 330 feet wide has been worked out clean, and in it and various other mines of the lode veins ranging from 65 to 200 feet wide have been worked out in the same manner. The ore of the vein in the Consolidated Virginia, above referred to, furnished an average yield of $126 in silver and gold to the ton. Such ore is too valuable to be utilized for chamber walls as principal supports, as is done in most of the mines of the world.

The enormous pressure resulting from the weight of the overlying formation, augmented by the absence of the usual chamber walls as principal supports, is sustained by an elaborate network of costly timbering, which has been admired for its completeness, safety and structural strength by many of the most skillful mining engineers of the civilized world. Without vast quantities of massive timbers to keep the walls in place, and corresponding quantities of wood to generate power for pumping out the water, hoisting the ores, reducing and amalgamating them and retorting at the mills, the great bulk of the precious metals which the Comstock mines have poured into the lap of nations would never have been discovered, and its extraction would have been practically impossible. The constant requisitions of the Comstock mines upon the mountain forests have led to the christening of the lode as "The Tomb of the Sierras."

When the mines of the Comstock lode were discovered the surrounding mountains were sparsely covered with a growth of scrubby pines (*Pinus edulis*), commonly known as the Pinon or nut pine, interspersed with a stunted variety of red cedar (*Juniperus Virginiana*). These woods were the most valuable of all for fuel, being hard, resinous and fine grained, but were worthless for timbers and lumber, being too small. They supplied the wants of the mines during the prospecting and surface-mining eras, and as long as fuel only was wanted, but as soon as any considerable depth was reached the supply was entirely exhausted, and the most easily accessible forests of the eastern slope of the Sierra Nevada were encroached upon, and ever since then the forest line of these mountains has been pushed westward before the axe, until now it is west of the eastern crest of the Sierra range, and almost on a line parallel with the western shore of Lake Tahoe, and fairly within the limits of the State of California.

Timbers, lumber and wood have been chiefly supplied in late years to the Comstock mines from the southern portion of the Lake Tahoe basin, on the California side of the State line. The wood and logs are first transported about twelve miles by rail to the lake shore at Bijou, the railroad extending over piles 1790 feet out into the lake, to a depth of water where the steamers and barges can moor alongside of the track. The wood is unloaded from the cars on barges, which have a carrying capacity of from 75 to 140 cords each. The logs are dumped from the cars into the lake and enclosed in boom timbers, forming immense rafts, and then towed by powerful steamers to the eastern shore of the lake. At this point the logs are sawed into timbers and lumber, which, with the firewood, are reloaded on cars and transported up a long incline to the summit over another railroad about ten miles long. At the summit it is unloaded and is conveyed through a flume about twelve miles to the wood and lumber yards at Carson City, Nevada, and from there it is taken by rail twenty miles to the mines, making a total distance of sixty-five miles from the forest, over two rugged mountain chains. From the forest to the mines the timber, lumber and wood are necessarily handled thirteen times, but the arrangements are so methodical and complete that the whole system is operated with mechanical regularity and precision. The flume is V-shaped, with a carrying capacity of 600 cords of wood a day, and it will transport the heaviest mining timbers as well as lumber and cord wood.

To the present time 120,000 acres of the Sierra Nevada's choicest forests around Lake Tahoe, and 75,000 acres around the headwaters of the Carson river, have been denuded to operate the mines. This area was practically all heavily timbered, and when it is considered that it equals an expanse of land 305 miles long by one mile wide, it will be apprehended that there is good reason for calling the Comstock "The Tomb of the Sierras."

From January 1, 1880, to January 1, 1891, 249,756,000 feet of timber and lumber were shipped to and used in and about the Comstock mines. During the same period 100,776,440 cubic feet of wood were consumed, and to the latter amount should be added 11,224,000 feet consumed by the Carson river mills, auxiliary to the mines, making a total of 875,316 cords. For the decade commencing January 1, 1870, and ending January 1, 1880, the timber, lumber and wood used cannot be ascertained with exactness, but a conservative estimate by men most familiar with the facts fixes the figures at 425,000,000 feet of timber and lumber, and 268,800,000 cubic feet of wood, to which should be added 10,240,000 cubic feet used in and about Carson river mills.

A moderate estimate of the average price paid at the mines for timber and lumber since 1870 is $23 a thousand feet and for wood $10 a cord, so that the Comstock mines since 1870 have used wood and timber to the total value of $46,072,548.

The consumption of forest products by the mines for the period between the discovery of the Comstock lode and 1870 can hardly be approximated, as there are no data for that time obtainable, but $55,000,000 is probably a moderate estimate of the entire cost of timbers, lumber and wood used in and about the Comstock mines from the date of their discovery until the present time.

The seemingly endless labyrinths of timbers in the Comstock mines, when ignited and beyond control, make a subterranean fire which burns and smoulders for years. Many lives have been lost in the mines by reason of these fires, but none are recorded as having been lost because of any inherent defect in the timbers or system of timbering. The size of the timbers used varies from the huge pieces sixteen inches square and twenty-four feet long to the smaller pieces eight inches square used in cribbing. The species used are chiefly yellow pine (*Pinus ponderosa*), fir (*Picea magnifica*) and cedar (*Thuya gigantea*), of which the latter is found in such small quantities as to be hardly worth considering. Fully two-thirds of the whole amount used is yellow pine, about one-third fir, and less than one per cent is cedar. Yellow pine is a favorite timber with mine carpenters, on account of its exactitude in joining. Cedar is inferior to no known timber, not even excepting redwood, for its lasting qualities underground. Yellow pine has been taken from the lower levels of these mines so compacted by the enormous pressure it has withstood as to have a density and weight exceeding those of lignum-vitæ, and has been made into paper weights and other beautiful ornaments. None of the timbers in the Comstock mines have yet badly decayed, and their life there cannot be accurately determined. The heat and vapors of the mines surcharged with mineral atoms appear to have a decidedly preservative effect upon the timbers.

The area upon which the forest has been cut off to supply the mines is now growing up, principally in pine, but the second growth is so slow that it will require many years for it to attain a size sufficient for mining timber. The new growth is very thick, and on some of the lower slopes of the mountains, where it is over twenty years old, there are few trees ten inches in diameter, and the average diameter will not exceed six inches. In the Tahoe basin, which has been cut over principally within the last ten years, the young trees are about five feet high and will average about four inches in diameter. In the Sierra Nevada fir predominates on the northern slopes, where the snow remains the longest and the sun shines the least. On the other slopes pine largely predominates.

Aluminum: Quantity and Price for Last Ten Years.

The *Aluminum World* gives the following table showing the quantity and price of manufactured aluminum for each year from 1884 till 1893:

Date.	Pounds.	Price per pound.
1884	150	$9 00
1885	283	9 00
1886	3,000	9 00
1887	18,000	3 27
1888	19,000	3 42
1889	47,468	2 04
1890	61,281	1 55
1891	150,000	66
1892	259,885	66
1893	330,620	75

WRITING to the Union, Or., *Scout*, a Cornucopia man says: "We know the mines of Baker county are all running and the mines of Union county (confessedly the best in the State) are all idle. Why? Because the Baker papers keep their mines before the mining world and their articles are copied all over the West, especially in the MINING AND SCIENTIFIC PRESS of San Francisco."

Canadian Lumber.

Canadian lumber resources will undergo a very exhausting drain during this year and next. The present tariff system of the United States admits lumber free, but, as this tariff is exceedingly unpopular, and as the voters of the Republic in November last pronounced against it in unmistakable terms, it is taken for granted that it will be in operation only until 1897 at the furthest. Acting on this belief, all Americans owning wooded lands in Canada will do all that lies in their power to strip those lands before a new tariff shall be enacted that shall place a duty on imported lumber. They will strain every nerve to rush their Canadian trees into lumber, and to rush the lumber over the border. In this they will be imitated by the Canadians who own wooded lands. All of them will hasten to take advantage of the free markets here. The result will probably be a larger inroad into the forests of Canada during 1895, 1896 and 1897 than was ever before made in three years. The movement will send a good amount of money into Canada, to be sure, but the money will hardly offset the loss of forested area, and the percentage of it that may be classed as profit will actually be very small. Some Canadians, having an eye to the future, do not like the situation at all. They in reality consider the destruction of the Canadian forests an unmixed evil. On this side of the border the movement will work a present financial and industrial hardship, but in the broader sense it will be a benefit to the United States. The great cut for the next three years in Canada will be made on all the most accessible forest tracts, and, after those tracts are cleared, there will be an increase in the cost of Canadian lumber, by reason of greater expense necessary to move it from the remoter tracts to the shipping points. American owners of Canadian limits are slashing right and left, and when, at the end of the free-lumber period, they lay down their axes, they will have converted many square miles of forest into stumpy, chip-covered wastes, on which great fires will feed. Canada has got a free-lumber market now in the United States, but it will in the end prove to be a dear investment for Canada.—The Lumber World.

THE largest derrick in the world is said to be that used in the granite quarry of C. E. Taynton & Co., at Barre, Vt. Its mast is 99 feet high and is held by 10 guys, each running out about 200 feet to heavy anchorages. The boom can swing around a circle 142 feet in diameter, and, like the mast, is built of Phœnix columns, such as are used in structural iron work in buildings. The loads are hoisted by means of a steel wire rope 1¼ inches in diameter, and the boom itself is handled with a similar rope of three-quarters of an inch diameter. Over a mile of steel rope was used in rigging the derrick, and its weight, exclusive of the rope, is about fifty thousand pounds. It is operated by means of a hoisting engine, and so well are all the parts designed that a pull of 300 pounds at the end of the boom will revolve the whole appliance when the boom is horizontal and loaded with 37½ tons. The derrick has been tested with a load of 57½ tons, although designed to carry only 40 tons; and if the ropes were heavy enough the remainder of the apparatus has sufficient strength to carry loads of 80 tons. It replaces a derrick which had a mast and booms of very large sticks of pine, but the largest which could be procured were unable to raise with safety the heavy loads that had to be handled occasionally in the quarry.

TO REPAIR a feed or other water pipe, mix a moderately stiff putty from red and white lead with boiled linseed oil, and work into it some hemp chopped into short lengths; apply it over the crack in a moderately thick mass; then wrap some strips of canvas parceling round the rope tightly, and finish by sewing marline hard over the parceling.

Power, Mining, Milling, Smelting, Concentration and Leaching Machinery; Return Tubular and Water Tube Boilers, Corliss Engines, Jones' Mechanical Stokers, Hoisting Engines, Riedler Air and Gas Compressors, Riedler Pumping and Blowing Engines, Cornish Pumps, Roots Blowers, Copper Converters, Pyritic Smelters, Horseshoe Roasting Furnaces, Comet Crushers, Crushing Rolls, Stamp Mills, Shoes, Dies, Perforated Metals, Sectional Machinery, Huntington Mills, Frue Vanners, Bridgman Samplers, Concrete Mixers, Heavy Machinery and Mine Supplies. = = Write for Catalogues

John Taylor & Co.
Importers and Dealers in
Assayers' Materials,
Mine and Mill Supplies.
Also Chemicals, and Physical, School and Chemical Apparatus.
63 & 65 First St., Cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.
M.C.C.² BATTERSEA
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.
Agents of the **Denver Fire Clay Co.** and for the **Morgan Crucible Co.**, Battersea, England. Also for **E. G. Denniston's Silver Plated Amalgam Plates.** The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.
JOHN TAYLOR & CO.

DEWEY & CO., 220 Market St., SAN FRANCISCO,
PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY & CO., Patent Agents, 220 Market St., S.F.**

Business College,
24 Post Street, - San Francisco.
FOR SEVENTY-FIVE DOLLARS
This College Instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.
A Department of Electrical Engineering
Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

Market Reports.

The Markets.

SAN FRANCISCO, March 14, 1895.

A further drop in lead and copper, and an advance in silver, characterized the week. The assertion again finds credence that silver is sure to ascend. There is increased interest in the prospect for recognition of its demands.

The demonetization of the silver dollar twenty-two years ago has always heen as much of a historical puzzle as "The Man in the Iron Mask."

No bill was ever passed to demonetize silver. Silver was demonetized by a trick, and not more than two or three men in the city of Washington knew when it was done or within a year thereafter, even, that it had heen done. This demonetization was the result of a combination among half a dozen of the leading gamblers of the gold board, which had its ramifications ahroad. The coinage committee of the House reported a "bill to codify the mint laws." The necessity for that codification was well known, and the chairman explained that no change had heen made in any way of laws, hut that the different acts hearing upon the mint had heen brought together under one section. The hill was not even read, except hy title. It was passed without one dissenting vote. In the section enumerating the different silver coins of the United States the word "dollar" was omitted, beginning "the half dollar," etc. No one noticed the omission. Even a careful reading of the hill hy every memher of Congress would not have revealed the trick to any one of them. No memher was thinking of the demonetization of silver. No memher had ever suggested such a thing. The silver dollar was at three cents premium over the gold dollar, and when the gold dollar was quoted at 116 the silver dollar was quoted at 119. The word had been striken out hy some member of the committee without the knowledge of his unsuspecting colleagues; hut who did it has never heen discovered. In after years each member of the committee on coinage expressly disclaimed any knowledge of the trick or that he knew or had heard that the word "dollar" had heen omitted. The bill went to the Senate, was referred to its committee on coinage, examined perfunctorily, reported by Mr. Sherman (the chairman) to the Senate, and passed hy the Senate on Mr. Sherman's assurauce that it made no change in the law, only bringing all the different laws together. After the hill was passed the secret that silver had heen demonetized was carefully kept. No memher of the Government knew it. Six months after, and again a year after, President Grant, not knowing that silver had been demonetized, advocated the coinage of more silver dollars. At that time there were none in the country. The Secretary of the Treasury also advocated the same thing. To their intense astonishment they were shown the report of the director of the German mint, in which he stated that America had demonetized its silver coinage. The statement had been laughed at as the blunder of a foreigner, hut upon an examination of the mint laws as codified under the act of the year hefore, it was discovered that silver had heen demonetized for a year. Every effort from that moment to this to take the hack track has heen defeated.

Mining Share Market.

SAN FRANCISCO, March 14, 1895.

Comstocks opened quiet this week, advanced on Tuesday, had a sethack and held their own the days following. The "spring deal" has not materialized yet, though, as far as the real basis is concerned, the mines are in better shape uow than for some time hefore. Bodie Con. sold up to $1.45, exhihiting the most streugth of any on the list.

A gentleman from the Comstock, who visited the Eureka mill, tells the *Enterprise* that the Chicago syndicate which bought the tailings and recently completed the plant at the Eureka mill, is making a success out of the prospect. Eighty-eight per cent of the assay value of the tailings is heing saved aud everything is running in a prosperous manner.

At the anuual meeting of the Hale & Norcross, the following was adopted:

WHEREAS, The Supreme Court of this State has decided that the rule as to declaring dividends is, "That the apportionments of the net earnings to the payment of cash dividends is largely one of policy intrusted to the discretion of the directors"; and whereas, this corporation is a judgment creditor for more than $1,000,000 in the case of M. W. Fox vs. this compauy and others, which said judgment has heen appealed from and the said appeal has been argued and submitted to the Supreme Court;

Now, therefore, we, the stockholders of said corporation, do herehy authorize, empower and direct the trustees or directors of this corporation, in case judgment shall he affirmed in whole or in part to declare dividends to the stockholders immediately upon the collection of said moneys of the whole amount of said collection, less the debts and claims against said company, and the further sum of $25,000 to he retained for the use of the company and the dead work of the same.

At the delinquent assessment sale of the Sierra Nevada Mining Company, held last Monday, 784 shares were offered for sale, for non-payment of the assessment.

At the delinquent assessment sale of the Gould & Curry Company, on Tuesday, 1100 shares were offered.

Articles of incorporation of the H. P. Taylor Mining Company have heen filed. Principal place of husiness, Sau Francisco. Capital stock, $500,000, with W. Patterson, H. P. Taylor Jr., J. H. Smith, D. T. Cole and A. C. Hammond as directors.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 5, 1895.

535,162.—WHOD SHAPER—G. H. Carlson, Hoquiam, Wash.

535,320.—CONVEYOR—W. B. Comstock, Oak Bar, Cal.

535,322.—SEWER FLUSHER—P. B. Donahoo, Oakland, Cal.

535,058.—THILL COUPLING—W. L. Frazer, National City, Cal.

535,329.—MOTOR—J. Gambetti, Stockton, Cal.

535,100.—BURGLAR ALARM—J. B. Gill, S. F.

535,108.—MARLINE SPIKE—A. Helgesson, Portland, Or.

535,246.—HAULING SEINES—R. D. Hume, Gold Beach, Or.

535,253.—CAR COUPLING—J. C. Look, San Jose, Cal.

535,254.—CAR COUPLING—J. C. Look, San Jose, Cal.

535,260.—PULVERIZER—W. B. McPherson, Victor, Cal.

535,130.—WINDMILL—P. A. Norberg, Roslyn, Wash.

535,297.—ELECTRIC RAILWAY—A. Rosenholz, S. F.

535,302.—TRACK CLEANER—A. J. Smith, Stockton, Cal.

535,231.—SEAT FASTENER—C. G. Taylor, Farmington, Wash

535,125.—SCHOP—W. Vincent, Los Angelcs, Cal.

535,151.—CAR COUPLING—C. Whitmore, Stockton, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SECTIONAL CONDUCTOR SYSTEM FOR ELECTRIC RAILWAYS.—Alfred Rosenholz, San Francisco, Cal., assignor of one-half to Samuel J. Clarke and Harvey S. Browu of same place. No. 535,297. Dated March 5, 1895. This invention relates to improvements in electric railways in which the conducting wires are adapted to pass underneath the ground, and it is adapted to be used in conjunction witb a tuhe or tunnel either built specially for an electric railway, or the tuhe of a cable railway may he used when it is desired to transform the cable road into an electric road. It consists of a main conductor enclosed in tuhes surrounded hy a non-conducting cement, yokes fixed to the interior of the conduit or tunnel and adapted to support the adjacent euds of the conductor tubes at points where the switches are introduced between them, switches consisting of non-conducting casings fitting over the main conductnr hetween the ends of the pipes, a non-conducting tape nr film enclosing the conductor where it emerges from the tuhes, sleeves surrounding the conductor nnd screwing into the ends of the tubes, insulating collars journaled to turn upon said sleeves and fitting into the sides of the tuhular insulated casing which projects at right angles from the conductor, said casing supporting a trolley wire at its inner closed end, with a connection hetween said trolley wire and a contact plate in the interior of the casing, a soft iron core fixed to the main conductor and exteuding within the casing to a point adjacent to the contact plate thereof, an insulated wire having one end connected with the main conductor coiling around the core, with the opposite end connected with an insulated contact plate at the end of the core, wherehy contact is formed between the two plates when the trolley wire is depressed by a passing trolley, and contact hetween the two plates is broken hy a counterbalance weight at the opposite end nf the casing which raises the opposite end after the trolley has passed, so that the electric current is transferred from the main conductor through the intermediate conducting devices to the car while tbe car is passing a certain point and is then at once cut off.

AUTOMATIC SEWER FLUSHER.—P. B. Donahoo, Oakland, Cal. No. 535,322. Dated March 5, 1895. The object of this invention is to provide a means for periodically and automatically flushing and washing out sewers or other discharge pipes, with a novel means for utilizing the manbole well as a reservoir for the collection of water for flushing purposes and discharging said water in a body so as to produce a strong flow through the sewer. It consists of the combination with a sewer and a manhole and well of an opening connecting the well with the sewer, a hase removably fitted into a flanged frame whicb is set in cement surrounding the openiug, a valve seat formed near one end and a valve adapted to close the opening, a bucket hinged near the opposite end below the hase adapted to tilt about its hinge, a tuhe extending through the base above tue bucket to deliver water therein, a rope or chain connected with the buckot and with the valve and a pulley or segment over which the rope or chain passes wherehy the downward movement of the bucket raises the vnlve. Water is delivered into the manhole through a supply pipe, the flow heing regulated so that the water will fill the well to the point of discharge at auy desired time, as once or twice a day or once a week, or other suitable or desired time. The water flowing into the tube passes down into the tilting bucket heneath; and when the bucket has been filled, the weight is sufficient to cause it to tilt about its hinge, pulling up the counterbalance weight upon the other end of the rope or chain, and this allows the water to discharge suddenly in a flood until the bucket is emptied. After this has taken place, the weight of the counterbalance will raise the bucket to its origiual position, and the chamber or well will again fill and discharge as hefore described.

PENDULUM MOTOR.—Johu Gambetta, Stockton, Cal. No. 535,329. Dated March 5, 1895. This invention relates to a dovice which is applicable for the propulsiou of pumping or other machinery or for the driving of a vessel through the water. It consists of a swinging pendulum suspended within the vessel and mechanism through which the oscillations of the pendulum are communicated to drive the propeller or otber machinery. Wben mounted upon a vessel, the pitching and rolling of the vessel serves to move the pendulum, and power is applied from the pendulum fulcrum shaft through pinions, racks and gears, with suitable intermediate pawl and ratchet mechanism, so that the alternate oscillations of the pendulum are transferred to produce continuous rotary motion of the propeller shaft or other machinery in one direction.

PRUNE PRICKER.—A. L. Bancroft, San Francisco, Cal. No. 534,776. Dated Feb. 26, 1895. The object of this device is to provide an automatically operating mechanism through which the prunes pass hy gravitation and alternately fall a short distance, and are then arrested upon a surface provided with sharp perforating points so that the impact will perforate the skins. The invention consists of an inclined chute either stationary or rotary, so arranged that tbe fruit passes from it by gravitation, the angle at which the chute or cylinder is placed regulating the speed with whicb the fruit passes and the force with which it strikes the projecting points which line the bottom and sides of the tube or chute. If a tuhular carrier is employed the fruit may be lifted by suitable arms or cleats, heing carried part way up the sides, and then falliug hy gravitation to the bottom so as to insure its heing properly perforated. In conjunction with this are open channels or bars between which any dirt and leaves are allowed to escape, and the various sizes of fruit may also he graded hy similar arrangement nf bars.

FRUIT GRADER.—Antonio Cerruti, S. F., assignor of two-thirds to Fontana & Co., S. F. No. 534,783. Dated Feh. 26, 1895. This machine separates the fruit according to size, and it consists of traveling separated carriers mounted upon end supports and moving in lines which diverge from one end to the other, one of said carriers moving at a different rate of speed from that of the other carrier. Tbe carrier consists of endless traveling bands of suitable material aud construction—in practice ropes have been found to serve the purpose. The end supports consist of suitahle pulleys and the carriers travel in divergent paths from the head to the foot of tbe machine, so tbat the space between them gradually widens from the upper to the lower end. The carriers are in pairs, and there may he as many pairs as may be desired for any suitable capacity. Meaus are provided, lying in the path of the fruit, for temporarily arresting the movement of the same, wherehy its position hetween the carriers may be changed. These means consist of flexible strips which do not obstruct, hut tend to momentarily arrest the fruit, thereby giving the carriers a better opportunity to turn it into proper position.

A DEVELOPED GOLD MINE IN PAY.

A WHOLE OR PART OF ONE-EIGHTH INTEREST (TREASURY STOCK) FOR SALE.

The right man offered a seat in the Board of Directors.

Address KENYON, Box H, tbis office.

Coast Industrial Notes.

It is estimated that the orange crop of southern California is worth over $4,000,000 this year.

—The Oakland Preserving Company will soon add a meat-packing department, which will give work to an additional 200 hands.

—A handsome catalogue is received from the Bay City Iron Works, Fremont and Mission streets, who are making a specialty of architectural ironwork.

—The National Iron Works have turned out a flyer for the Alaska Improvement Co.—a 40-foot steam launch, with a 30-H. P. engine. She goes north on the bark Harvester.

—The statement of the earnings of the Atlantic & Pacific for the month of January, as given out by the receivers, shows a deficit of $172. This is a gain of $63,654 over that of January, 1894.

—Subscriptions continue to the San Francisco and San Joaquin Valley road. Mayor Sutro generously continues to assure the projectors they have his "moral support," whatever that is.

—Chas. C. Moore, for several years secretary of the San Francisco Tool Co., has succeeded to the business of that defunct concern and will continue the business at 32 First street. Mr. Moore is an experienced man and should do well.

—The International Telephone and Telegraph Company has been granted a franchise to erect and maintain a line from Spokane, Wash., to the British Columbia mining country, a distance of over 200 miles. The company is capitalized at $200,000 and will at once begin construction.

—At the annual meeting of the Mechanics' Institute the new Board of Directors organized by electing the following officers: President, A. S. Hallidie; vice-president, George Cummings; corresponding secretary, Marsden Manson; recording secretary, Charles E. Mooser; Treasurer, First National Bank. The next fair will open in the pavilion on the 13th of August.

Bonner & Hammond of Missoula, Mont., who have contracted with the citizens of Astoria, Or., to build a road from that place to Globe, about sixty miles, will soon establish headquarters at Astoria and begin surveys for the line. It is stated that the bonds of the company have been negotiated. Work must begin by the first of next month, and the road is to be completed by October, 1896.

—An experimental shipment of Pacific coast wheat from Portland, Or., to Liverpool by way of Panama has been undertaken by F. H. Peavy of Minneapolis, Minn. Mail advices from Colon say that a trans-shipment has been effected at the isthmus without injury. The new route saves a long voyage around the Horn. It was a question whether the wheat would not be spoiled by the weather it would encounter crossing the isthmus.

—Representatives of California iron industries will take prominent part in the Manufacturers' Convention next Tuesday. Three papers will be presented: "Loyalty Toward One Another and Home Industries," "Freight Rates," and "Specialties in Manufacturing." The committee to draw up the papers consists of James Spiers of the Fulton Iron Works, G. W. Dickie of the Union, Robert S. Moore of the Risdon, J. W. Kerr of the Phœnix Foundry, and W. P. Sullivan of the Pacific Rolling Mills.

—The following is a statement of the Tacoma Smelting and Refining Company for February, 1895: Number of men employed, 62. Pay roll, $4,683.16; woodchoppers and teams, $336; total, $5,019.16. Product—Bullion, 2000 bars weighing 205,577 pounds; copper matte weighing 115,600 pounds. Contents—1,186.81 ounces gold at $20.67, $24,631.36; 27,089.05 ounces silver at $.60, $16,253.43; 229 532 pounds lead at $3.022 per cwt., $6,943.34; 41,680 pounds copper at $.092 per pound, $3,959.60; total, $51,687.73.

The "free zone" of Mexico consists of a strip of land twenty kilometers wide, extending along the northern boundary line of Mexico, from the Pacific ocean to the Gulf of Mexico. The strip is about 12½ miles in extent and probably includes all the cities and towns in Mexico situated on the border line, the principal ones of which are Nogales, Juarez, Piedras Negras, Matamoras, Nuevo Laredo and Tia Juana, Lower California. Merchandise exported hence has never been absolutely free of duty in what is termed the free zone, but is, and has been, subject to duty at the rate of ten per cent ad valorem—a rate, however, much less than the regular Mexican duties.

The check-raising swindle on the Union Pacific has forced the company to either pay in currency, as in old days, or else adopt a paper that is chemical proof. The company is convinced that chemically prepared paper safeguards against this class of swindles is a myth. They succeeded in finding an acid that would remove the best Stanford ink from the face of checks, at the same time not even destroying a fiber of the Underwood chemical paper upon which the checks of the Union Pacific are printed. The checks which were raised failed to show a single erasure mark, and the amount of the checks in figures in the right-hand corner, as well as the written amount in the body of the check, were wiped out as completely as if a cloth had been used in removing dust from a table top.

Assessment Notices.

FAIRFAX VILLA COMPANY. Location of principal place of business, San Francisco, California. Location of works, Fairfax, Marin county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 8th day of February, 1895, an assessment, No. 2, of one hundred dollars ($100) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 56, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of March, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY the 16th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. STADTFELD, Jr., Secretary.

Office—Room No. 56, No. 309 Montgomery street, San Francisco, California.

CHALLENGE CONSOLIDATED MINING COMPANY. Location of principal place of business, San Francisco, California; location of works, Gold Hill, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the nineteenth (19th) day of February, 1895, an assessment (No. 18) of Five Cents (5c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the twenty-sixth (26th) day of March, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the sixteenth (16th) day of April, 1895, to pay the delinquent assessment, together with cost of advertising and expenses of sale.

By order of the Board of Directors.

C. L. McCOY, Secretary.

Office—Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

BOOTH GOLD MINING COMPANY. Location of principal place of business, San Francisco, California. Location of works, Auburn, Placer county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the eighteenth day of February, 1895, an assessment (No. 5) of Two (2c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, Room No. 28, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on WEDNESDAY the seventeenth day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. K. SPINNEY, Secretary.

Office—No. 310 Pine street, Room No. 28, San Francisco, California.

IOWA MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia City, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 6th day of March, 1895, an assessment (No. 20) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 2, 419 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 9th day of April, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 27th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

K. L. THOMAS, Secretary.

Office—Room 2, 419 California Street, San Francisco, California.

DELINQUENT SALE NOTICE.

INYO MARBLE COMPANY OF CALIFORNIA. Location of principal place of business, San Francisco, California. Location of works, Inyo, Inyo County, California.

NOTICE.—There are delinquent upon the following described stock on account of assessment No. 26, levied on the 21st day of January, 1895, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
M. J. McDonald, Trustee.	294	5,000	$500 00
M. J. McDonald	453	250	25 00

E. L. Wagner.	227	1,000	125 00
L. P. F. Waller	525	220	27 50
L. P. F. Waller	530	100	12 50

And in accordance with law, and an order of the Board of Directors, made on the 22d day of January, 1895, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, No. 214 Pine street, on THURSDAY, the 21st day of March, 1895, at the hour of 2 o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

JABEZ HOWES, Secretary.

Office—214 Pine street, Room No. 5, San Francisco, California.

NOTICE OF POSTPONEMENT.

In accordance with an order of the Board of Directors of the Dumbarton Land and Improvement Company, adopted at a regular meeting, held on the 26th day of February, 1895, the day of sale for unpaid Assessment No. 7 is postponed to THURSDAY, March 28th, 1895, at 2 P. M.

JABEZ HOWES, Secretary.

Office—214 Pine street, Room 55, San Francisco, California.

DELINQUENT SALE NOTICE.

REED MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Ferguson Mining District, Helene, Lincoln county, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment No. 1, levied on the 31st day of December, 1894, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
J. H. Isham, Trustee	6	500	$10 00
J. H. Isham, Trustee.	7	2,500	50 00
J. H. Isham, Trustee.	8	50	1 00
J. H. Isham, Trustee	9	50	1 00
J. H. Isham, Trustee	14	33,400	668 00
J. H. Isham, Trustee.	13	73,000	1,460 00
J. H. Isham, Trustee.	18	75,000	1,500 00
Geo. G. Reed.	15	12,857	257 14
Geo. G. Reed.	17	2,143	42 86

And in accordance with law, and an order of the Board of Directors, made on the 31st day of December, 1894, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 33, Tenth Floor, Mills Building, San Francisco, California, on WEDNESDAY, the third (3d) day of April, 1895, at the hour of 11 o'clock A. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of the sale.

J. H. ISHAM, Secretary.

Office—Room 33, Tenth Floor, Mills Building, San Francisco, California.

UNION IRON WORKS,
SACRAMENTO, ... CALIFORNIA.

ROOT, NEILSON & CO.,
—MANUFACTURERS OF—
STEAM ENGINES, BOILERS,
And all kinds of
✦ ✦ MACHINERY FOR MINING PURPOSES.
Flour Mills, Saw Mills and Quartz Mills; Machinery Constructed, Fitted Up and Repaired.
FRONT STREET, Bet. N & O.,
SACRAMENTO, CAL.

✦ ✦ PLACER ✦ ✦
Amalgamators,
Dredgers,
Shovels.
Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.
Highest possible gold yield insured.
Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.
Crushing, Pulverizing, Concentrating and other machinery also built.
Investigation solicited.

MINING, MILLING & SMELTING SUPPLIES

Practical Hydraulics.
A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators.
By P. M. RANDALL.
This work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.
TABLE OF CONTENTS.
The following brief abstract of the contents will give an idea of the branches of the subject treated:
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulæ and Rules; Flow of Water Through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels. Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.
Price, $2.00, postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

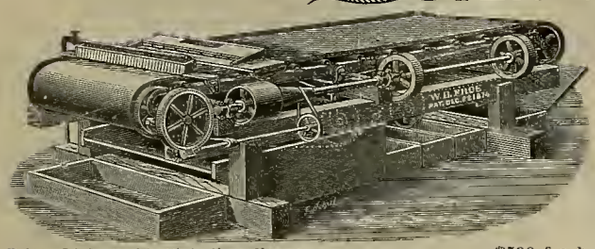
MINE BELL SIGNALS.
Adopted, Used and In Force in Accordance with State Law.
FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

FRUE ORE CONCENTRATOR.

OVER 4000 IN ACTUAL USE.



Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; March 31, 1891.

GLADSTONE MINING COMPANY, FRENCH GULCH, Shasta Co., Cal.
C. J. Clark, M. E., Gen'l, Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
C. J. CLARK, Gen'l Supt.

Wind Pressure on Buildings.

A number of instructive experiments on the effects of wind pressure upon buildings and other structures have been made by Prof. Kernot, and communicated by him in a paper read lately before the Australasian Association for the Advancement of Science. Wind for the experiments was obtained from a fan of special design that gave a practically uniform pressure over a considerable area. The effect of vertical walls on the pressure exerted by wind upon the roofs surmounting them was plainly indicated. A roof slanting 60° experienced a reduction of two-fifths in the pressure it sustained when a vertical wall exposed to the same air current was below it. A roof slanting 45° lost four-fifths, and one slanting 30° showed no pressure. The cause of this is that when the side of a house is struck by a current of air traveliug at right angles to its surface the motion is turned into an upward one, and the air slides off the wall in a vertical direction with such force that it wholly or partly takes with it the upper horizontal current that would otherwisc strike the roof. A parapet still further protects the roof from the effects of wind, carrying the oncoming air higher still.

When the old California shares, 108,000 in number, were divided into 540,000 shares, and each share sold at $250, people thought that was a "fancy price" for mining shares. But all that is now exceeded in the present London price of South African mining shares. A leading mining paper has a column of mines advertised. One mine is stocked at 2,500,000 shares, and each share is quoted at £110 offered and £112 asked. When $550 a share is asked (and probably paid) for 2,500,000 shares of stock in a mine, it looks as though the stock gambler and his victim had at last met.

The diminished gold yield of January in the Witwatersrand, South Africa, district, is locally accounted for by the statement that the "imported cyanide contains alkaline sulphides," which absorb the oxygen from the water, and lessens the power of solution. Any kind of sulphides would have a retarding influence, but if the present inflation in mining stock shares is not to be punctured, a more plausible reason for the falling off in the gold yield there must be given the mining public.

The Broken Hill Proprietary Co. have cut down their annual expenses nearly $750,000. The *Australian Mining Standard* is authority for the statement that "the average cost per ton of ore treatcd has now beeu reduced from £6 15s 4d to £2 3s 7d." There is probably some mistake in these figures.

It is to be borne in mind that mere naked possession, work and occupation of a mining claim without complying with location laws will not hold as against subsequent locators of the same ground who do comply with those laws.

The Dayton, Nev., Dredger.

So much interest has been manifested in the illustrated account of the operations of the Carson River Placer Mining and Dredging Co., at Dayton, Nevada, in the issue of February 16th, '95, that we have had our engravers prepare another illustration of the barge, screen and machinery of the company in operation.

The accompanying engraving, like the previous one referred to, is reproduced from a photograph of the plant at Dayton, and gives a very good idea of the machinery that, after years of costly experiment, is now expected to add many millions to the solid wealth of the world.

BARGE AND SCREENING MACHINERY OF THE CARSON RIVER PLACER MINING AND DREDGING COMPANY, AT DAYTON, NEVADA.

A new astronomical observatory is to be erected on Mt. Lowe, southern California, at an altitude of 3500 feet. It will have a refracting telescope with sixteen inches aperature, presented to the director, Dr. Lewis Swift, by the people of Rochester, N. Y., who came to know him through the Warner observatory in that city. Dr. Swift will also have a thirty-seven-inch reflector, but, as that class of telescopes yields only about five-eighths the light obtaiued from a refractor, it will be inferior to the big Lick glass at Mt. Hamilton.

The stone for the mammoth arch in the Parrott building, on Market street, this city, is quarried from the Pioneer quarry, near Corvallis, Or. The arch is over fifty feet across.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Barge and Screening Machinery of the Carson River Placer Mining and Dredging Company, at Dayton, Nev., 177; The Hendy-Norbom Concentrator, 183.

EDITORIALS.—Wind Pressure on Buildings; The Dayton, Nev., Dredger; Miscellaneous, 177. An Important Decision; Miscellaneous, 178.

SCIENTIFIC PROGRESS.—Water: An Important Event; 1900 Not a Leap Year, 184.

MECHANICAL PROGRESS.—Fire Tube and Water Tube Boilers; Iron Cheaper in the United States Than England; Photography Under the Sea, 185.

ELECTRICAL PROGRESS.—Electric Lighting in Mexico; Electric Life Buoys; Electric Light Photography; The Medical Electrician, 188.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 186-87.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 190.

MISCELLANEOUS.—How to Stimulate the Iron Industries of San Francisco; Concentrates, 179. The Greatest Ore Field; Idaho's Mineral Output for '94, 180. Characteristic Features of California Gold-Quartz Veins, 181. Labor as a Factor in Manufacturing; Utilization of Water Power; Personal; Books Received, 182. The Hendy-Norbom Concentrator; Ore Sorting in Colorado; Quartz vs. Placer, 183. Wire Silver Produced by Artificial Means; Money Value of Hands and Fingers. Advice to Young Engineers and Inventors, 188. The Mineral Hydrocarbons, 189. Recent Patents, 190. Coast Industrial Notes, 191.

RAILWAY companies' reports are to the effect that few if any paid dividends in '94, and the outlook is none too encouragiug iu '95. 'Tis different in the mining world. The mining dividends in the couutry in '94 outweighed in the aggregate the railway dividends, which is uot so much of an anomaly as it might appear to be at first glance.

THE Goveuor has signed the bill ameuding Section 527 of the Code of Civil Procedure by adding: "No iujunction granted prior to the actual trial of the cause wherein it is granted shall continue in force for a longer period than twelve months from the time such injunction was granted, except by consent of the parties, or unless the cause be set for trial upon its merits."

"FOR Private Circulation Only," the Journal of a London Scientific aud Literary Society, is received, iu which, through thirty nicely printed pages, are argued reasons for its existence. Information is also vouchsafed us that in our particular case the usual requiremeuts as to reference, educational qualifications, etc., will be waived, and merely on the receipt of fifty dollars, we will be enrolled as a "Fellow," aud become the possessor of a handsome silver badge "about the size of an American $20 piece, artistically executed, with name, and laurel wreath of merit." Isn't there some other society in London that essays to protect guileless Americans from such scientific distinction? There certainly ought to be.

THE increased demand for mining machinery includes inquiry for gold stamp mills. The common and usual arrangement is five in a battery, millmen generally considering that an odd number best induces an even distribution of pulp, and five being a convenieut number. Stamps range in weight from 350 to 1000 pounds. Nevada reports the heaviest in use and Colorado the lightest. There is a certain definite proportion between the weight of the shoe, stem, tappet and boss. In au 800-pouud stamp the shoe would weigh about 125 pounds aud the die 100 pouuds. As a general thing, too thick a die occasious a breakage of screens. The drop in a gold mill is froun 12 to 20 inches. The present competitive contest, previously referred to, will go far toward determining the practical nature of the respective claims made.

IT is a fact not susceptible of successful contradiction that there is to-day no branch of busiuess that offers such superior inducements to the investor as the mining industry. While Bradstreet's aud Dun show that ninety-five per cent of mercantile ventures are failures, iu gold mining there is uo competition, a sure market, and the same opportunity for the exercise of skill, iutelligence and economy that exists in any department of business. There is a certain and uncertain amount of distrust arising largely from hazy ideas that all mining partakes, necessarily, of a gamble, and that it is not as "sure" as other business ventures. Memories of sharp practice in some mining companies, or of extravagant management in others, have much to do with those uotions. With such matters legitimate mining has nothiug to do. Such things are inseperable from auy and all lines of busiuess or iuvestment. In uo other business has scieuce, ecouomy and improvement made profit more possible, and iu no other pursuit are there greater probabilities of reward for the judicious employmeut of capital.

IN this issue appear in their entirety three papers read by practical, experienced men at the Manufacturers' Conventiou, now in sessiou in this city. They well illnstrate the tenor and purpose of the meeting, and the consciousness of their truth is the best reason for the occasion that elicits such utterances. The remarks of Messrs. Scott, Spiers, Moore, Brayton, Hallidie and others are to the point, and the requirements of the day are fully recognized. One of the strongest points is made by Mr. Spiers, where he states that labor is the chief factor of cost, and that transportation is but a part of labor cost. And Mr. Moore tersely outlines "the need for co-operation in behalf of the common good," and "that the maxim of 'every one for himself aud the devil take the hindmost' is not good business policy." Our interests are so bound up together that only in taking the largest and broadest views of these matters can the best permanent results be secured. Then, too, as Mr. Moore says, we are on the threshold of a new era, and only by recogniziug the changed condition of affairs can present untoward circumstances be overcome. That these things are plainly stated in the Manufacturers' Convention is good evidence of the practical benefit that can justly be expected to result. The problem is a wide one, into which State pride and sentiment do not enter as largely as State interest and necessity.

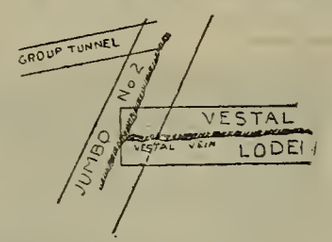
IN no other branch of miuing has so little improvement been made upon original methods as in drift gravel miniug. In a few instauces machinery is beiug used to cheapen and expedite the extraction of gold-bearing gravel, but the general manner of working is substantially the same as years ago. In later days the tunnel is larger and less sinuous and the timbering more substantial. Posts from 10 to 24 inches in diameter are used: caps from twelve iuches upward. The old square tunnel is no longer used, the general dimensions being in the main tunnels seven feet on the bottom, 6½ to 7 feet high and 3½ feet at the top in the clear. The posts thus placed prevent that rapid crowding in at the bottom noticed when set perpendicularly in soft ground. Steel and iron T-rail is used considerably, varying from 16 to 42 pounds to the yard. Though the first cost is considerable, it is found in the end more economical than strap rail laid on wooden stringers. The only noticeable difference in the car is that it is considerably larger, holding more than a cubic yard, and weighing, when full, nearly two tons. The wheels are rigid and the steel axles turn in babbitted, self-oiling boxes. Devices for hauling the cars and securing ventilation have not varied much from original methods. Drift mining is important iu the system itself and the occasioual necessity under existing conditions of resorting to that method of mining in the case of a hydraulic claim. It sometimes takes the place of the latter system where water is scarce, where there is no dump room or where the deposits are low and it would be impracticable to move the whole by piping. It is carried on more like vein mining than hydraulicking, although used only in gravel. Some California drift mines have made very large returns, the Union, in Sierra Co., having a record of $625 per lineal foot in a 2400-foot claim. The conditions of expense vary greatly, ruuning from $1 to $6 a yard. At the Hardscrabble, in Siskiyou Co., the cost per cubic yard has been summarized as follows: Labor, $1.00; timber, .31; lights, .05; horse feed, .02; wear and tear, .12; total, $1.50. In another drift mine the possibility of powder, falls, etc., would increase that average, while the "wear and tear" item is very indefinite and elastic.

An Important Decision.

The United States Court of Appeals at St. Louis, Mo., has made a decision in the case of the Enterprise Mining Co. vs. The Rico-Aspen Con. M. Co., of Colorado, that reverses a former decision on tunnels and tunnel rights. In the decisiou, which since its promulgation was held to be sound law, tuunel owners had only 250 feet either side of the liue of the tunuel. Last week's decision reverses this, giviug tuuuel locators 1500 feet in any direction from the liue of the tunnel. The Court says: "From the time of location and commeucement of his tunnel, under Section 4 of Act 10, 1872 (Section 2323, Revised Statutes), the owner has the inchoate right to possessiou of every blind vein or lode within 3000 feet from the face of such tunnel on the line thereof that was uot known to exist when the tunnel was located and commenced, contiugent only on the diligent prosecution of the work on the tunnel and subsequent discovery of the vein or lode therein."

This is a final decision: no appeal lies to the United States Supreme Court, aud is one of the most important mining law decisions in years, as it definitely decides the rights of mining tunnel locators.

In '79 the Group Tunnel site was located, and for several years excavation was prosecuted. Subsequently the Vestal Lode mining claim was located, based upon the discovery of a veiu at the surface running parallel with the Group tunnel, and about 200 feet from the tunnel line. It will be noticed in



the diagram that the Vestal did not cross the tunnel line, and also, that any veins discovered in the Group tunnel would necessarily cross the Vestal Lode claim. A United States patent was issued to the latter. The Enterprise Mining Co. acquired title to the Group tunnel iu '90; in '92 an ore vein was cut in the tunnel; by driftiug it was found to cross the patented Vestal location, which had passed into the possession of the Rico-Aspen Co.

The Enterprise Company were extracting ore from the Jumbo No. 2 vein, within the lines of the Vestal claim, while the Rico-Aspen Co. were running a drift from a shaft on its Vestal claim so as to reach Jumbo No. 2. Conflict in the mine resulted in litigation; suit was instituted by the Rico-Aspen Co., and an injunction obtained preventing the Enterprise Co. from continuing the removal of ore.

The Circuit Court gave a decree to the effect that the Rico-Aspen Co. was entitled to all that portion of the Jumbo No. 2 vein lying within the Vestal location.

The Enterprise people appealed with the result as above, the Court of Appeals holding that the owner of a tunnel claim is under no obligation to adverse an application for patent for a lode mining claim based upon a surface location, unless the vein has been discovered in the tunnel crossing the surface location, and that the tunnel owner, upon discovering a blind vein crossiug the tunnel, is entitled to the possession of the vein for 1500 feet in one direction or the other from the tunnel, or may, if he chooses, locate the claim partially upon one side and partially upon the other side of the tunnel.

While the decision deals with a Colorado statute of 1861, it in general fixes the principle "that the measurement of the leugth that may be claimed by the tunnel begins at the point of discovery, and measures full 1500 feet in any manner that the discoverers may choose, and this without any reference whatever to surface measuremeuts," which seems to be equity as well as law.

THE coming season promises to be one of great activity in California gold mining—placer, drift and quartz. Gold is the one thing in California to-day that is worth as much as it was a year or five or tweuty years ago, and California is the one State in the Uniou in which gold is the plentiest and the easiest to fiud.

Concentrates.

SILVER is again on the rise.

THE Telegraph mine, Bingham, Utah, is under bond for sale.

TEN STAMPS are to be added to the Santa Rosa mill in Pinecate district.

DEER LODGE, Montana, reports several gold strikes southeast of that town.

A SULPHURIC ACID PLANT is to be built at Deadwood, S. D., to work pyritic ore.

OVER $80,000 in refined gold and silver bullion is missing from the Carson, Nev., mint.

THE OWNERS of the Montana gold mine, in the Black Hills, claim to have $3,000,000 in sight.

THE Senator mine, Mojave Co., Arizona, has been sold to M. W. Flournoy, of Albuquerque, N. M.

THE Mercur Company declared a dividend of $25,000 last week, the first one since last December.

THE absence of Thos. Couch in Arizona has delayed consideration of the bids for the thirty-stamp mill at Mariposa.

CANDLES went up to $9 a box at French Gulch during the recent snow blockade on the Trinity Mountain and Yreka road.

MOHAVE, says the *Miner*, is the only county in Arizona where silver mines are paying working expenses right along.

WESTERN AUSTRALIA recently announced a whistling snake, whereupon British New Guinea comes to the front with a whistling spider.

THE Cispus mining district in the eastern portion of Lewis county, Wash., is attracting attention. Recent assays show from $300 to $500 a ton.

THE new gold find on the desert near Indio, Cal., is in a granite formation, nine miles north of Tingman & Holland's mill in Pinon Mountain.

A GIANT-POWDER EXPLOSION in the Verde mine, Minas Piretas, Sonora, Mexico, last Monday, instantly killed four miners and fatally wounded another.

COLONEL R. F. MORTON, a prominent mining man of Sonora, Mex., was instantly killed by a Chinaman last Monday while he was eating breakfast at the Cananea mines.

SO FAR, $227 have been contributed to the treasury of the Placer County Miners' Association by the miners at the Hidden Treasure mine, Sunny South, Placer county.

DENVER proposes to have a mining and industrial exposition in '96. At a preliminary meeting D. H. Moffat handed in a $50,000 check. A few men like him can make it a success.

A SUIT involving $3,000,000 comes up for trial at Denver next week. It is the famous Bassick mine in Colorado. The property is equipped with machinery of an estimated value of $475,000.

THE Hughes Creek Mining Company, of Lemhi, Idaho, has been organized by Minneapolis men, under the laws of Minnesota, with a capital of $150,000, divided into 3000 shares of $50 per share.

CHARLES MORTON, employed as a shaft repairer at the Hector mine, Sutter Creek, was killed instantly in the shaft of that mine last Saturday afternoon. He was working alone at the 300 level.

LAST WEEK Supt. Casserly at the Alaska mine, Pike City, Sierra Co., captured a specimen thief who was running away with a sack containing ore worth $600. He was allowed to go, minus his booty.

THE Utica mine continues yielding its little $250,000 a month. If they had that mine in the Witwatersrand, S. A., it would be capitalized in London with 20,000,000 shares being placed at £100 each, par value.

THERE is a probability that work will be commenced on the Montana State School of Mines this summer, and that active steps will be taken toward putting Butte into actual possession of the institution which she now has on paper.

THIS is going to be an early season for Montana prospectors and quartz mining operations, but it is feared the placer miner will go unusually short of water about July 1, unless he is situated to control snow water at an early period.

TWO MEN AND A WOMAN have been arrested at Deadwood, S. D., charged with stealing gold amalgam from the Homestake mills. The men were employed in the mine and are reported to have secured $50,000 worth in a period of three years.

THE Reno, Nev., *Journal* says that lumber for sluice-boxes is being hauled out to the placer mines discovered on the northwest side of Peavine mountain. The diggings are not very extensive and are all located. The gold is coarse and of fine quality.

MINES near Banner, San Diego Co., are flourishing. The Ella mine is working day and night shifts. Tracking for 1000 feet of tunnel has arrived. The Blue Hill tunnel is in 700 feet. The old Redwood mine will soon be provided with new pumping machinery.

"MOUNTAINS of gold" and "hundred-ounce nuggets" are now announced from Western Australia. The steamship company which has an advertisement in every interior paper in the State, offering cheap fares to Coolgardie, probably has nothing to do with those reports.

THE Arizona *Republican* says: "Either the Holy Terror mine in South Dakota is exceptionally appropriately named, or the operators are holy terrors when it comes to lying. The mine is reported to have produced $20,000 worth of gold in five days." Arizona can do a little itself in the line of mendacity.

THE Chicago syndicate which recently bought the tailings of the Eureka mill on the Carson river, Nevada, and built a plant for working them, is making a success out of the prospect. Eighty-eight per cent of the assay value of the tailings is being saved and everything is running in a prosperous manner.

LOUIS BLANDING says that the statement that the largest gold nugget ever found on the Pacific Slope was worth but $21,000 is erroneous. He says that J. J. Finney found a lump of gold about six miles from Downieville, Sierra county, on the 21st day of August, 1857, that weighed a fraction over 5000 ounces. Gold was at that time worth about $18 an ounce, which would make the value of that single lump something like $90,000. Blanding further says that there is no doubt that this nugget was the largest piece of gold ever found. The next largest was from the Ballarat (Australia) gold field, and was worth $60,000.

THE Banner mine, thirty miles north of Idaho City, Idaho, is said to be the richest silver mine in that State. Its total output is over $1,000,000. Six years ago it produced $90,000 in a month. The force has recently been cut down, as it does not pay to mine refractory ore, even though it runs from 100 to 300 ounces per ton.

A BRITISH COLUMBIA mining journal describes the formation of the Surprise mine in the Slocan district as follows: "Cambiran, principally schistose argileaux lime and plumbiferous shales with obtusial dykes of feldspathic and auorthyte porphyry." It would seem as though "the component parts were highly metalliferous."

ROBERT DUNCAN, JR., superintendent of the Alaska-Treadwell, writes: "I have received your letter, and in reply beg to say that this and every part of Alaska at this date is overrun with men looking for work, which they cannot obtain; therefore, it would not be good policy to come to Alaska at this time looking for work."

A MINERAL known as proustite, a crystallized ruby silver, assaying from 1200 to 6000 ounces to the ton, and carrying more or less gold, has been discovered several times in Colorado of late. It resembles cube iron very much, has a cherry-red hue and does not turn blood red when scratched with a knife. This makes it richer, as its quality is nearly a pure mineral and is not susceptible to a flaky scratch.

A MINER named Geo. Dey was recently killed at the Gold Ridge Con. mine by an explosion of giant caps, and Superintendent Phelan, coming to this city on behalf of the company, offered to the dead miner's mother to bring the remains here, buy a cemetery lot and pay all the funeral expenses, or have the interment take place in the Sierras and give her what the funeral would cost. She chose the latter, and the company promptly paid her $250.

THE total output for January of the Montana Mining Company was 6470 tons of ore, which contained 2620 ounces of gold and 20,550 ounces of silver. The estimated realizable value of the same is $63,300. The expenditures were as follows: Working expenses on revenue account, $35,200; outlay on developments, $13,900; legal expenses, $900; extraneous and traveling expenses, $1700; machinery, etc., $1000, making a total of $52,700, and leaving a net result of $15,000 for the month.

THE best gold story of the week comes from Utah, where, a telegraphic legend asserts, a young school teacher and his pupils, while engaged in geologic research, found gold galore in the San Juan river. The regular "three old California miners" were on hand to take charge, and the result of the first day's work in the bed of the stream yielded $2300. The next best comes from the Pichaco district, a long letter stating that "white gold" has been found there which "sells readily for $24 an ounce."

MARTIN DALGREEN, manager of one of Governor Grant's mines in Old Mexico, writes of a very peculiar method they have down in that country of impressing miners into the service. The men receive the enormous stipend of 67 cents a day, and are required to take 80 per cent of this out in trade at the company's store. It is but natural that there would be a scarcity of miners at the end of every payday at these prices, even among the Greasers. But they have a very merry way of drumming up recruits, that, while successful in that country, would probably raise trouble if tried on in any mining camp in this State. Every Monday morning the mounted police are sent out to scour the country for men to work in the mines, and those who refuse are sent to jail.

THERE are many different kinds of mines, but there is only one known salve mine, and it is located near Rock creek, Wyo. The mine consists of a grayish colored clay, nearly as hard as a rock, and when placed in water it softens into a salve that will heal cuts, burns, inflammation, and cure bad hoofs in horses, and heal all kinds of wounds, except love's. Determined not to be outdone by Wyoming's new salve mine, Colorado comes to the front with a honey mine. The *Golden Globe* says: On the north side of North Table mountain the bees have for years used the caves and crevices in the rocks as their home. Hundreds of pounds of honey have been taken out of these places the past few years. Many tons of this wild honey have been mined from our mountains, and to get at it the rocks in places had to be blasted away.

THE California Miners' Association, through A. H. Ricketts, chairman of Committee on Mineral Lands, has filed general protests against the patenting of about 500,000 acres of land to railroad companies in this State. The protests go to the Marysville, Los Angeles and Redding districts and oppose the patenting of mineral land. The publication of this effort on the part of the railway companies to absorb mineral land in this State was first made in these columns last October. The attention of the California Miners' Association convention was directed to it at the meeting the following month and vigorous measures adopted to forestall such wholesale grab. Since then the matter has become one of widespread notoriety, and the committee in charge of the matter has spared no effort to thwart the moves of the railway company to acquire title to several hundred thousand acres in this State manifestly mineral in character.

Two decisions have been made by Secretary of the Interior Smith, wherein a former decision in the Pike's Peak case has been overruled. The decision affects mining cases where disputes arise between placer and lode claims. Secretary Smith decides when it has been ascertained by the Department or determined by a court of competent jurisdiction that a lode or claim exists within the boundaries of the land covered by a placer patent, that such lode claim was known to exist at the date of the application for such patent, and was not applied for by the placer claimant, the land in the lode is reserved from the operation of the conveyance, and patent may issue for such lode, if the law has been in other respects fully complied with. The first decision is in the case of N. J. McConnell, known as the South Star Lode case, and the other is the Plain View Mining and Milling Company and Charles H. Peters vs. James Freeman, known as the Freeman Placer case.

How to Stimulate the Iron Industries of San Francisco.

ROBT. S. MOORE, Risdon Iron and Locomotive Works.

The theme assigned me is the "Iron Industries of this City and State," and I am invited to do in ten minutes what all the brains engaged in those industries have not been able to accomplish in as many years. I am requested to suggest a plan, to outline a policy, by which the said industries may be rescued from lethargy and brought to a state of permanent prosperity.

I doubt if the best way to approach the subject is to regard the iron industries by themselves. They, like every other important branch of manufacture, are necessarily dependent upon the general state of trade, and so intimately connected with environing industrial conditions that, only by the improvement of those conditions, can the iron industries be improved.

When mining is depressed, business dull, real estate dead, population stationary or declining, and moneyed men afraid to invest in improvements, the iron men need not look for activity in their line. This is so apparent as to make the statement a truism; yet the truism needs to be forced home on business men who are prone to take narrow views when their individual financial interest is involved and to lose sight of the dependence of their special line of work upon the general welfare.

To my mind, the impulse which gave birth to the idea of convoking this convention augurs much good, not alone for the iron industries, but for *all the industries* represented on this floor.

This impulse arose from the perception of the need for co-operation in behalf of the common good; and when that spirit is stronger in this community than it is now; when California's men of business come to realize, with a vividness that shall control action, that they are all in one boat, we shall then have the "New California," about which so much is being said and written, and of the approach of which this convention is one of the cheering signs.

One of the principles on which the new order of things will be based will be a clearer understanding of the soundness of the business doctrine—that Californians should be for California, and that the maxim of "every one for himself and the devil take the hindmost" is not good business policy. It is action on this maxim that has kept California a colony in tributary bondage to the East.

Turning aside from generalities, I would advise a permanent organization of this Manufacturers' Convention, to be controlled in its work by a body of responsible men, who, by painstaking, intelligent investigation, shall first ascertain the causes of the prevailing stagnation in each particular line of industry, and then present the remedies.

I believe in the efficacy of legislation to help us. We need law to compel home patronage by wealthy corporations in our own and adjacent cities. These corporations exist by favor of law and depend on the California public for their support. Nevertheless, we in the iron trade all know their habit of ignoring their neighbors when they have work to give and purchasing abroad because they can, for the moment, save a few dollars thereby. Theiron industries would at once feel the stimulating effect of the change if these corporations were not penny-wise and pound-foolish. The extent to which they are so is known only to those who suffer most directly by their course.

Hardly a week passes that we do not see proposals advertised and contracts for machinery let to Eastern firms because the latter can underbid our local manufacturers. On the Oakland side of the bay a large corporate water works has just been completed, the entire pumping and boiler equipment of which was brought from Milwaukee. At San Jose the contract for a pumping plant of five million gallons capacity was recently given by the city to a New York concern, and local bids were not entertained or even solicited, and already the representatives of leading Eastern iron firms are opening offices in San Francisco eager for work of every nature and kind.

Gentlemen, this is all wrong; but it is the California custom of cutting her own industrial throat. Hundreds of like cases could be cited from the past, and it would be time well spent to enumerate them in order to prove that our main trouble is with ourselves, and therefore removable by ourselves.

The labor unions have set their employers in the iron industries an example which we should have the intelligence to follow. They have done the best work ever accomplished in the direction which plain self-interest, common sense and practical public spirit dictate. A few years ago, these workmen waited upon the San Francisco supervisors and succeeded in having inserted in street railway franchises a clause compelling the companies to patronize home industries. A similar clause was incorporated in the contracts for the dome of the New City Hall. The plan worked admirably. Law stepped in between unreflecting greed and local public interest, and thus thousands of dollars worth of work was kept at home through the efforts of this handful of organized labor.

In order to compete successfully with the East; in order to become a manufacturing State on a large and flourishing scale, California must of course approach more nearly to Eastern conditions. At present we are all keyed up too high. The pioneer tradition of "easy come, easy go," born of lucky chances and full pockets, still survives and hinders. We are all disposed to live beyond our means and to despise those economics which are mandatory upon an industrial community if it would compete successfully with energetic and intelligent minds elsewhere.

Without dwelling upon the disastrous effects of low freights from the East upon all our industries, I will simply state we are on the eve of a change in these unjust, unnatural and killing conditions, with a bright prospect that we shall soon come by our own again. The new Valley road, with Claus Spreckels at the helm, is, if I may adopt figurative language, the herald of the New California, blowing a blast on its horn which has awakened the whole State and will arouse it still further. This road, it is certain, will start other roads, deprive the East of its artificial privileges in our field and give home energy, home enterprise, home brains and home money a fair chance to do California's work and get their just reward.

To sum up then the needs of the iron industries are not peculiar. They call for co-operation; for patriotic law, where that is practicable; for wise economy in methods of production; for adjustment to Eastern conditions; for recognition of the truth that there must be more public spirit amongst manufacturers and a greater readiness to comprehend that their welfare is bound up indissolubly with the welfare of the whole community.

The Greatest Gold Field.

Written by DAN DE QUILLE.

California is taking a new departure in gold mining. For some years after the war upon the hydraulic miners all kinds of mining was suffered to languish. The old and paying quartz mines and drift diggings continued to be worked, but very little prospecting was done. Though the war of the people of the valleys was only against parties engaged in hydraulic mining, the effect was to discourage and disgust the people of the mountains, who were stigmatized as "outlaws" and "bandits." Some left the mountains and went into the towns of the valleys, others remained and for a time strove to keep themselves and their families by working their mines in secret by night, but spies from the valleys were constantly on the watch and so many were arrested, fined and imprisoned that at last hydraulic mining was as good as killed. It was argued by the people of the "cow counties" that the shutting down of the hydraulic mines would make but little difference in the gold yield of California, as the men of the mountains would at once turn their attention to quartz mining, but an awful falling off in the annual product soon appeared.

Some few tried quartz mining for a time, but the majority clung to their hydraulic claims, out of which they strove to make a living by working them as drift diggings. Men with families dependent upon them could not take chances by roving the mountains in search of paying quartz veins; they were obliged to make sure of some gold, however small the amount, therefore they drifted, creviced, panned and rocked about in their old diggings. All kinds of mining were much demoralized and California began to lose prestige as the great gold-producing State of the country. For several years mining was so much discouraged in California and so great was the decline of that industry that the verdict in the East was that the State was "played out" as a gold producer. The men of the valleys "got on top" and people of the older States were soon led to believe that the "Golden State" was no longer of much value, except for its grain fields and orange groves. From the very first the shutting down of the hydraulic mines was sorely felt by many San Francisco business men, but the agriculturists had the "pull" and the great industry of mining languished. The old, developed, paying quartz and drift mines continued to be worked, but few new enterprises were undertaken, and the little prospecting in progress was conducted in a superficial and desultory manner.

In San Francisco there were always men who longed for the old full flow of gold from the mountains and who were earnestly stirring to revive the waning industry of mining. In this they have been so far successful that the working of hydraulic mines is again permitted under certain conditions—the impounding of the tailings flowing from the diggings. Although but a few of many hydraulic mines have started up under the new law, the beginning made has had a good effect. Interest has again been awakened in the mining industry and prospecting has been resumed in good earnest. The men of the mountains feel that the ban of outlawry has been removed from their class and some recognition given them under the law by the restoration of a part of their old rights. Soon again the mountain towns, as of old, will be the most prosperous in California. Soon again property in the mountains will have value and the mining industry will take its old place to the front.

Gold-bearing quartz veins now constitute about the only property outside of the great financial centers in which there is any encouragement to invest money. In all other industries except gold mining, under the present monetary system, prices of products are steadily going lower and lower. It is only the product of the gold mine that shows increase of value in this time of tumbling values. This being the case, and paying gold mines being about the only kind of property in which it is safe to invest, the gold-bearing veins of California are being looked after. The demand for paying mines has given new life to prospecting and many wonderfully rich discoveries are now being made in the old "Golden State."

To-day there is more gold in the great gravel deposits of the mountains of California than has ever been taken out. Wonderful deposits of the yellow metal to be found in a thousand places in the State, and a hundred years hence rich discoveries will continue to be made, as in many sections the face of the country is covered with such a depth of soil that hundreds and thousands of veins of gold-bearing quartz, great and small, are hidden from sight. From time to time, as the years roll on, one after another these veins will be found and their virgin contents brought to light. Where one large, rich vein is found, parallel veins of the same character almost always exist, therefore one discovery in a new section of country nearly always leads to many others.

Some wonderfully rich deposits of gold have been discovered in the quartz veins of California, but probably there is to-day lying hidden somewhere in the mountains of the State a far bigger bonanza of the yellow metal than has ever yet been found or ever dreamed of. And this great store of gold may to-day be somewhere almost peeping out through the soil of the surface. Of all the gold fields of the world, California is that of the greatest possibilities. The hundreds of millions in dust and nuggets that have been gathered on the surface from the placer deposits show this. All the gold found in the placers, gulches, creeks and rivers—with millions on millions more of fine dust washed away into the sea in the course of ages—was but the result of the decomposition and erosion of the croppings or upper parts of the quartz veins above in the great gold belt lying along the western face of the Sierra Nevada range of mountains. Those millions found in the surface deposits of sand and gravel were but the golden seeds cast off by the blossoming and ripening auriferous quartz veins above. All the gold in the veins below the level of the face of the rock constituting the solid surface formation of the country—the "country rock"—remained in place, and where it has not been discovered and mined out, to-day still lies in the veins.

The quartz veins of the Sierra Nevada mountains constitute the source of all the gold found in the California placer deposits. The hundreds of millions found in the placers, creeks and ravines were but the loose gold shed in the course of ages by the weathering and wearing down of the exposed tops of the veins of auriferous quartz. It is therefore evident that, great as was the amount of gold found scattered about the face of the country, the main store of the yellow metal must remain behind in the veins. For many years the attention of the majority of the miners of California was turned to the placer mines—few meddling with the quartz veins—and even to-day there remain unworked and unexplored whole mountains of auriferous gravel and vast fields of such placers as are usually worked by hydraulic process. Even now the full harvest of surface gold is far from being gathered. Hundreds of millions still remain in the gravel of the hills and flats and in the sands of the streams.

Still, for years some have devoted themselves to the development of the quartz mines of the State, and deep, genuine mining in the veins that are the source of the surface gold may now be said to be fairly under way. At many points along the great mother lode immensely rich mines have been opened and are found to pay steadily year after year. Although some of the oldest of these mines have attained great depth, they still yield well and the veins show no sign of giving out.

In the vicinity of these rich mines, on and along the mother lode, is a fine field for prospectors. The paying mines show a "fertile belt," and in a fertile belt are nearly always to be found parallel veins. The best country in which to prospect is one that has yielded an immense amount of surface gold, which shows good strong sources of the yellow metal in quartz veins. Thus it will be seen that California to-day is the best country in the world for a miner who wishes to prospect for gold quartz. Looking at the immense amount of gold that has been gathered on the surface, then counting the quartz veins that are known and worked, it becomes evident that there must still be hundreds of rich veins that remain to be discovered. There are to-day better chances in California than in South Africa, Australia or any other country on the face of the globe. The chances for making a big find are as good as in any other gold field in the world. The gold deposit that lies undiscovered and untouched is as big to-day as in the days of "'49." Then, the miner can at the present time obtain provisions and all other supplies at cheaper rates in California than in any other gold-producing country in the world. In no State in the Union can a man live better for a small amount of money than in California.

For some years past, until recently, there has been very little prospecting done in California. While prospecting was active in Colorado, Utah, Idaho and other regions to the east, it was almost at a stand in California. The men of the mountains were so worked upon that they gave little thought to prospecting, and most of them were so enraged against the people of the "cow counties" that they would hardly have touched a quartz lode had they known it to be filled with gold. They resented having their hydraulic mines shut down by the valley ranchers and being left to "dig quartz or starve."

Recently, however, the miners are again coming to the front. Eggs, butter and potatoes are now more plentiful in the valleys than gold, and the miners are no longer chased about in the mountains as "outlaws" and "bandits." Almost every week we now hear of new and rich discoveries in quartz. These are not up in the wilds of the mountains, but in and about the old camps, as at Grass Valley, where the first quartz mining in the State was done. There is no better place in which to prospect than in the belts of fertile country about the old camps in Nevada county, Mariposa, Sierra, Tuolumne and other counties up and down along the great mother lode. Even close to the towns all has not been found that the earth contains. Surprising finds are frequently made in and about even the oldest camps. These finds are generally by some outsider or "greenhorn." People living in a mining camp think they known all about the place, and seldom bother with prospecting. When a camp is new, prospecting may be pretty lively for a time, but it soon dies out and that is the end of it until a big find is made by some blundering tenderfoot who does not know quartz from granite or gold from iron pyrites.

In California, in the fertile belts, even the smallest of quartz veins are worth looking after. A vein, however small, that shows gold, is worthy of careful exploration, as it is liable to prove to be a feeder of a large hidden lode, or, if not, may lead to a rich pocket at no great depth. If a vein shows gold at all it is pretty sure to contain pay at some point. Once a prospector becomes well acquainted with a section of country he soon finds a place where he can make enough money to "clear his teeth," and having taken root on the range, he will be in hard luck if he does not within a year or two hit upon a good mine—perhaps tumble into something amazingly rich.

In prospecting, the man who selects a good section in a strong gold belt, and then settles down and makes himself thoroughly acquainted with his surroundings, will be much more likely to succeed than one who runs from place to place expecting to catch something on the wing. There are still hundreds of millions to be found in California, and during the coming summer we are likely to hear of many wonderful discoveries being made. Most of these will be near the old camps, for as yet there is not much scouting up into the high Sierras.

Idaho's Mineral Output for '94.

Frank F. Church, assayer in charge of the United States Assay Office at Boise, has completed his report, showing the total product of gold, silver and lead for the State during the year 1894.

The report points out that the leading mining districts in the State now attracting general attention are the De Lamar and Silver City mining districts of Owyhee county and the Cœur d'Alene district of Shoshone county. Within these districts are a number of mines which have few, if any, equals for richness and quantity of ore beds. Especially is this true of the silver-lead mines of the Cœur d'Alene district, which has increased its output over the previous year, notwithstanding the continued dull market for the product.

Of the placer ground of the Murray district, Shoshone county, he says the output has been steady and substantial. The gold-bearing quartz mines are also quite productive and are very promising in character.

The Warrens district, Idaho county, is fast taking the lead in profitable quartz and placer mining, and will add materially to the production of the State for the present year.

The many good ledges in Boise and Lemhi counties have been developed within the year to such an extent that their profitable operation is no longer a question.

The Seven Devils district, in Washington county, is exceedingly rich in copper, but has been developed meagerly on account of the lack of transportation.

The flour gold to be found in great quantities on the famous Snake river has attracted unusual attention, and has contributed largely to the increased production of the State.

The following is a detailed statement of the output:

GOLD.

Counties.	*Fine Ounces.*	*Value.*
Ada	739	$15,276
Alturas	836	17,282
Bingham	1,788	36,961
Boise	15,859	327,935
Cassia	1,108	22,904
Canyon	1,029	21,271
Custer	1,253	25,902
Elmore	5,139	106,232
Lemhi	13,217	273,230
Logan	1,407	29,085
Idaho	12,116	250,460
Owyhee	37,915	783,773
Shoshone	17,531	362,398
Washington	750	15,504
Other counties	1,000	20,672
Totals	111,687	$2,308,775

SILVER.

Counties.	*Fine Ounces*	*Value.*
Ada	204	$264
Alturas	294,207	380,380
Bingham	225	291
Boise	24,876	32,162
Cassia	195	252
Canyon	220	284
Custer	71,120	91,951
Elmore	2,708	3,501
Lemhi	4,552	5,855
Logan	604	781
Idaho	11,832	19,176
Owyhee	1,004,792	1,299,096
Shoshone	2,343,314	3,029,671
Washington	12,000	15,515
Other counties	500	646
Totals	3,774,349	$4,879,855
Lead production		$2,605,450
Gold and silver		7,188,630
Total production		$9,793,080

For 1893 the production of the State, according to the Mint statement, was as follows:

Gold	$1,603,641
Silver	4,467,464
Lead	2,524,753
Total for 1893	$8,685,858
Total for 1894	$9,793,080
Actual increase	$1,108,222

REPORTS from Mexico indicate that silver production there is being pushed with vigor, and under various concessions which the Government has made new refineries and smelting works are going up, while the railroads make specially low rates to the coast, in marked distinction to the prohibitory rates which the California railroad system puts on silver sent here for shipment to the Orient.

Characteristic Features of California Gold-Quartz Veins.

Read before the Geological Society of America by WALDEMAR LINDGREN, December 29, 1894.

The gold-quartz veins of California, in spite of many local variations, form a remarkably well-defined type of mineral deposits, the salient characteristics of which it is intended to portray in this paper. The results, indicated in brief outlines, have been obtained during general and detailed mapping for the United States Geological Survey in the gold-bearing region of California.

The general map of California indicates the extent and distribution of the gold-quartz veins. Beginning in the peninsula range south of the Mexican boundary, the deposits continue in scattered form and with many intermissions up to Fresno county, a few of them also occurring at isolated points along the coast ranges south of San Francisco. In Fresno county they become more abundant, and in Mariposa county the auriferous belt rapidly widens. From here northward to the point where they are covered by the great lava fields of northeastern California the maximum development is obtained. In latitude 40° the gold deposits extend from the great valley on the west to the summits of the Sierra Nevada on the east. In a northwesterly direction the continuation of the gold-bearing area is found in Shasta, Trinity, Siskiyou and Del Norte counties in California, and its northerly end occupies the counties of Jackson, Josephine and Curry in southwestern Oregon. Volcanic flows and more recent superjacent formations cover the gold-bearing area toward the east and north.

A smaller auriferous belt of less importance runs along the eastern slope of the Sierra Nevada, beginning in Alpine county and continuing southward through Mono, Inyo and San Bernardino counties. Most of the deposits along this line differ more or less from the normal type of the western slope.

In the northern part of the Mexican peninsula and in San Diego county granitic rocks prevail, but in them are imbedded numerous more or less contact-metamorphosed areas of slates and schists of uncertain age. The gold-quartz veins usually occur in, or at least close to, these areas. The principal mining districts in San Diego county are Julian and Banner, in the central part, and Pinacate, near the northern boundary.

Granitic rocks, with smaller schist areas, continue through San Bernardino and Los Angeles counties. Placer deposits and smaller veins are found around San Bernardino mountain, as well as at several places in clay-slate near the summit of the range, in the central and northern part of Los Angeles county. Very scattered and isolated deposits occur in Ventura, Santa Barbara, San Luis Obispo, Monterey and Santa Cruz counties. In Monterey paying veins have been found near the coast at Los Burros, sandstone being mentioned as the country rock. A short distance north of Santa Cruz a few gold-quartz veins are said to occur in unaltered sedimentary formations. In Kern county there is a line of paying veins with a northeasterly strike, extending from Kernville to Tehachipi pass. Granitic rocks predominate, but contain a number of smaller schist areas, with which the gold deposits appear to be associated. The locality is of interest on account of the number of hot springs occurring near the veins. Tulare county contains but few quartz veins, but placer diggings are found along several of the rivers.

In Fresno county, again, several streaks and smaller areas of schists and slates occur in the main granitic mass; again, the quartz veins, which here attain greater importance, are closely associated with the former, though not exclusively occurring in them. Continuing northward for about fifteen miles to Mariposa, these belts of schists and slates suddenly widen, and at the same time begin to contain numerous and rich quartz veins. Between this region and the lava fields of the north lie the most productive gold-mining regions of California.

The western slope of the Sierra Nevada is from here northward occupied by a gradually widening belt of rocks, to which the name "metamorphic series" is usually given. It attains its maximum width in Butte and Plumas counties and continues across northwestern California and southwestern Oregon to the Pacific ocean. The eastern part and the summit of the Sierra Nevada are still occupied by the continuation of the southern granitic area, bordering upon the "metamorphic series," with an irregular and jagged contact line, along which evidence of the later origin and intrusive character of the granite may be frequently observed. The "metamorphic series," sometimes also referred to collectively as the "auriferous slates," is a very complex mass of rocks. It consists largely of more or less altered and highly compressed sediments, of an age ranging from early Paleozoic to late Jurassic, and bearing evidence of having been subjected to several mountain-building disturbances. Associated with these sediments are igneous masses—augite-porphyrite, diabase, serpentine, etcetera—also ranging in age from Paleozoic to late Mesozoic, though the greater mass of them appear to date from late Jurassic or early Cretaceous time. To a considerable extent these igneous rocks have been acted on by the dynamo-metamorphic processes, which also affected the sedimentary rocks, and are largely converted into crystalline schists. It may be said in general that the sedimentary rocks prevail in the eastern part of the metamorphic belt, while along the great valley basic, igneous rocks are found in the greatest abundance. The granitic rocks of the high Sierra Nevada are to a large extent *granodiorites*, the name adopted on the survey maps for a quartz-mica-diorite containing more or less orthoclase. In the metamorphic series there are many smaller masses of the same rock—the latest intrusions—which are usually but little affected by dynamo-metamorphic processes.

The intimate connection of the gold deposits with the metamorphic series or the auriferous slates has been recognized for a long time, and Professor Whitney emphasizes it repeatedly in his works. The auriferous region, indeed, corresponds closely with the extent of the metamorphic series. Even in the south, where the granitic rocks predominate, it has been shown that the gold deposits are usually connected with the shattered schist areas. Few gold-quartz veins are found in the granitic area, and then usually near the contact. Within the typical gold-bearing region the veins are distributed with remarkable impartiality, and occur in almost any of the great variety of rocks which make up the metamorphic series. They are found in granite, diorite, granodiorite, gabbro and serpentine; in quartz-porphyrite, augite or hornblende-porphyrite and diabase; in amphibolite and other dynamo-metamorphosed rocks; in sedimentary, more or less altered slates, sandstones and limestones. In Tertiary volcanic rocks gold deposits are only found on the eastern slope of the range. It is apparently impossible to formulate any law as to their lithologic occurrence or to say that they prevail in any one kind of rock in the metamorphic series.

Regarding the quartz veins of California, F. von Richthofen has made a frequently quoted statement, which in a certain sense may be correct, but which, unless qualified, is apt to lead to grave errors. It is as follows:

> The auriferous quartz veins "have in their occurrence clearly discernible connection with the extension of the granite. They are crowded closely at its contact with the metamorphic rocks, and occur here partly in the former, partly in the latter. The greater the distance from the granite, the rarer they become in the metamorphic rocks, and only occur as an exception where the influence of the outcropping granite would not be expected on account of its distance. In the same way they become less frequent in the granitic regions as the distance from the contact increases, and are, as a rule, entirely lacking in the interior of the large granite masses."

This statement cannot be accepted for the main granitic contact, which, on the contrary, except near Sonora, is remarkably barren of important deposits. In the larger part of the gold region a wide belt of Paleozoic slates, comparatively poor in gold deposits, separates this contact from the principal gold-producing districts. In very many places, however, the contact clearly marks the abrupt beginning of auriferous deposits, though perhaps poor and of small extent. The sudden change of recent and Tertiary river-beds from barren to auriferous when cutting across the contact is often very noticeable.

Though not applicable to the main granitic contact, the statement quoted is to a certain degree true of the smaller masses of granodiorite scattered through the metamorphic series, for it is very common to find the gold-quartz veins clustered near their contacts in the manner indicated. It is not so general, however, as to be called a rule or a law, for there are many included granitic masses the contacts of which are in no way remarkable for abundant deposits.

Dr. W. Moericke, who has recently published several very interesting papers on the gold deposits of Chile, has come to the conclusion that they are closely associated with acid. igneous rocks, and drawn a comparison between the occurrences of that country and California. In view of this, it may be well to emphasize the fact that the gold-quartz veins of California do not in their surface relation show any remarkable dependence on acid, igneous rocks. The great mother lode, for instance, is in location and occurrence of its ores in no way related to such rocks, they being, on the contrary, as a rule, distant from it.

Normal gold-quartz veins in diabase and augite-porphyrite sometimes occur far away from other rocks, although the larger areas of the former are, on the whole, rather barren.

Before beginning the discussion of the characteristics of the deposits, their age may be briefly touched upon. It has long been apparent and insisted upon by Whitney, von Richthofen and others that the quartz veins of California are of late Jurassic or early Cretaceous age, and the same authors have suggested that they probably owe their origin to thermal action following the granitic intrusion. For the larger number of the quartz veins this is undoubtedly true. It is certain that the majority were formed subsequent to the latest dynamo-metamorphism of the sedimentary and old eruptive rocks of the Sierra Nevada, subsequent also to the granitic intrusion. It is, however, also certain that some deposits antedate this period, for in the latest sedimentary member of the bedrock series there are conglomerates containing quartz pebbles and free gold, which appears to have been concentrated as placer gold at the time the conglomerates were formed. It does not appear easy to separate the earlier deposits from the later, but it is probable that they were neither very numerous nor very rich.

Again, the eruptive activity of late Tertiary time which was centered along the summit and on the eastern slope of the Sierra Nevada was followed by another period of thermal activity, and another line of gold deposits was formed. This intermittently recurring action confirms von Richthofen's generalization that a region once metalliferous is always metalliferous. Successive eruptions in such vicinity produce successive mineral deposits, while other eruptive centers are wholly barren of them.

It is desirable to eliminate a few deposits of a different type from the prevailing one. Most important among them are the *impregnations*, of which several examples occur in the Sierra Nevada and which may be of two types: First, zones containing grains of iron pyrites disseminated in fresh dynamo-metamorphic amphibolitic schists. Those zones are seldom strongly auriferous, but may enrich quartz veins passing through them, and are apparently similar to the so-called "fahlbands" in crystalline schists. These deposits are distinctly older than the principal quartz veins and contemporaneous with the dynamo-metamorphism which produced the schists from the diabase and other rocks. Second, impregnations of later date forming irregular zones, in which the massive rocks or schists have been decomposed and filled with secondary auriferous sulphides. These deposits are probably contemporaneous with the principal period of vein filling, and only a phase of it, in which the solutions, instead of following distinct fissures, permeated whole masses of rocks. The first of these types of impregnation is not of great economic importance, but the second sometimes affords large masses of low-grade ores.

Regarding the structural relations of the normal gold-quartz veins it should first be stated that they are fissure veins, and emphatically not so-called segregated veins or "lenticular masses" in the auriferous slates.

It is everywhere plain and evident that the fissures have been broken open subsequently to the metamorphism of the rocks. These post-Jurassic and post-granitic quartz veins form the latest chapter in the Mesozoic revolution in the Sierra Nevada.

Neither Whitney nor von Richthofen commit themselves to an expression of the "segregated" nature of the veins. A. Phillips, in his book on mineral deposits, mentions their affinity to fissure veins, although classing them as "segregated veins." All these writers, however, state that the veins nearly always conform in strike and dip to the inclosing slates. This has evidently led the authors of recent text books to class the California veins as "segregated." Thus Professor J. F. Kemp, in his "Ore Deposits of the United States," classes them as such with some doubt, while Professor R. S. Tarr, in his "Economic Geology of the United States," thinks that "in spite of the recent observations (by H. W. Fairbanks), it still seems as though these quartz veins must be of segregation origin."

Quartz veins like those Professor Tarr has in mind, formed by a sort of dynamo-metamorphic process, I am quite sure do not exist in the gold belt. The somewhat auriferous "fahlbands" in certain amphibolites approach nearest his conception. I am by no means prepared to deny, however, that there may be some minor ore bodies deposited in openings in the slate from silicious solutions derived from the immediately surrounding rocks; but if they occur, they are surely exceptions to the general rule. In altered quartzose slates, nodules and lenses of quartz seemingly of such origin frequently occur on a small scale.

This rule of "parallelism with inclosing slates" must unquestionably be rejected in a general description of the veins. It should first be pointed out that a very large number of veins, especially in the northern part of the gold belt, from Placer to Butte county, do not occur in slates or schists, but in massive rocks, such as diabase, granodiorite or gabbro, and among these a predominating direction of dip and strike does not exist. In slates and schists the veins often strike about parallel to the slaty cleavage—that is, northerly or northwesterly—but other directions are nearly as common. Only very exceptionally is there a strict parallelism in both strike and dip. The great mother lode, for instance, is parallel to the strike of inclosing rocks, but differs not inconsiderably from them in dip. Its character of fissure vein is clear and unquestionable, and has been justly insisted upon by H. W. Fairbanks. All directions and all dips are in fact represented among the California quartz veins, only dips below 20° and above 70° are comparatively rare. A general rule for strike and dip cannot be given; different laws guide them in different mining districts. The quartz veins are the expression of the greater and minor strains to which the Sierra Nevada has been subjected, and a study of the former will, to a considerable degree, illustrate the latter, which have certainly varied in intensity and direction from point to

poiut. Thus, to pick out a few illustrating examples, the veins of Ophir, Placer county, consist of two priucipal systems—one set of veius ruuing west-northwest and dipping south, while the other has a west-southwest strike and southerly dip, both cutting the surrounding schists obliquely to their strike and dip. At Grass Valley and Nevada City there is one system with a general northerly direction and dipping either east or west; another system courses east and west and dips north or south at varying angles. The surrounding rocks are here mostly massive. The veins in the vicinity of Sierra Buttes, Sierra county, show the greatest divergeucies in strike and dip. Equally variable are the veins about Sonora, Tuolumne county.

The force producing these fissures appears in most cases to have been a compressive stress acting at an angle more or less oblique to the horizontal. In some cases this force produced one large and prominent fracture, but far more commonly one or several series of fractures, or a sheeting of the country rock along which the auriferous solutions could circulate. Along the larger fissures cousiderable movement has taken place; but when the country rock has been sheeted, the motion along the individual joints has probably uot been very great. In many cases, when the direction of the movement could be proved, it has been found that a relative upward movement of the hanging wall has taken place. The force did not produce a single, sudden and catastrophic movemeut; on the contrary, it contiuued for a long time, resulting in repeated dislocations, as proved by the re-opening and refilling of some veins and by a sheeting of some veins, producing what is usually described as "ribbou rock." Recemented quartz breccias are also of common occurrence.

I should here like to mention one misleading circumstauce relating to parallelism of vein and country rock. When larger fissures are opened in massive rocks it is not at all uncommon to find the immediately adjoiniug wall rock converted entirely locally into schists parallel to the fissure, under the influence of the enormous shearing stress to which it has been subjected. Such veius would have the appearance of cropping iu pre-existiug schist masses and of parallelism in strike and dip with these. The coudusion to be derived from the relatiou of the veins to the larger, regionally metamorphosed schist masses is that the schistose structure antedates the formation of the veiu fissures, and that the forces to which these fissures are due, while bearing a general similarity to those manifested in the cleavage, often differed from them in directiou to a sensible extent.

Different rocks influence the character of the fissures to some exteut. In massive rocks they are apt to be straight, clear cut and well defined; in slates and serpentines there is often a teudency to spliuter into a network of cracks and fissures, extremely small, but often very rich. Iu such cases, the whole mass, country rock and vein, may be extracted and milled. Linked veins are common, and chambered veins sometimes occur.

Very loug and coutinuous veius are not common, aud in this respect the mother lode is rather au exceptiou. Only rarely can a quartz vein be traced more than a few miles, and many important veins crop out only for a short distance.

Labor as a Factor in Manufacturing.

JAMES SPIERS, Fulton Engineering and Ship-Building Works.

The manufacturing industry on this coast stands in the same relation to that of the East as the manufacturers of the United States do to those of Europe, with the important difference that the manufacturers of the United States are protected against those of Europe by a protcctive tariff and by prohibition in building vessels for the coasting trade, while we as against the East are not. In many cases protection is unnecessary, but in many others it is essential; and in regard to the building of vessels, if those of foreign huild were allowed to do coastwise trade, that industry would he entirely destroyed.

In manufacturing on this coast the only protection that we have is the difference between the freight rate on the raw material which we obtain from the East and that on the manufactured articles. The cost of any manufactured article is practically the labor which has produced it. Various metals or other materials may enter into its composition, hut, in either case, the fact remains the same, that the cost of the labor to produce it virtually makes its value. Take a piece of machinery, for instance: The material in it is iron, steel, brass, copper, habbitt or other alloys, and wood. The cost of the entire material in its native condition is insignificant. The ore from which the steel and iron are produced, while lying in Mother Earth unexposed, has but little value. When time and labor are used to discover the ore body and afterwards to sink the shaft from which the ore is taken, yon add to the value of the underlying metal. When it reaches the surface of the mine more bas been added to its value, due to the labor of mining. The labor of taking it from the mine's mouth to the furnace, with all tbe details of smelting and converting it into pig iron, still further adds to its value. When, after this, it is made into castings, into wrought iron, or converted into steel, its value is still further increased by labor. Labor then again takes hold of it and converts it into the different parts of a machine. The same is true in regard to all other metals and their alloys. The same is also true in regard to any wood that is used in the construction of machinery or other manufactures. When growing in the forest its value is insignificant.

From the foregoing statement it will he seen that wben a machine is produced its cost may be said to consist almost entirely of labor, plus the slight value of the material of which it is made when in its native condition.

The cost of transportation of material from one place to another, if analyzed, will also prove to be that of labor, so that when a piece of machinery is built in any of our workshops it represents the value of the labor put upon it, and the difference between that and the price for which it is sold represents the profit to the manufacturer, or, in other words, his labor. In the case of patented articles the difference between the value of the labor and the selling price is the manufacturer's profit, or his labor, and also a royalty due to the patent.

Precious metals, the value of which is due to their scarcity, etc., are not considered here.

On this coast a great deal of the material which we use comes from the East and has already acquired a value due to the labor of its production, with that of transportation added, so that when we take hold of it its value is more to us, by the cost of freight, than to our brother manufacturers in the East.

Fuel also is higher in value, due to tho long distance of transportation. As this is a large lumber-producing State, the cost price of the same should be in our favor. The cost of transportation of the raw material, as a rule, is less than that of manufactured articles and therefore somewhat in our favor. On the coast of California an artisan can do more work than he can in any of the Eastern manufacturing centers, on account of our superior climatic conditions. The cost of labor here is from 20% to 25% greater than that in the Atlantic States. This higher cost of labor is an inheritance from the early gold-mining period, when we had no transcontinental railroad by which the Eastern manufacturers could pour their goods into the State, the only means of transportation then being by the Isthmus of Panama, delivering goods in sixty days from New York, at large freight rates, and by the route of sailing vessels around Cape Horn, forming an excellent protection to our home industries. Under such conditions no large orders for machinery aud but little for specialties were sent East, while our own manufacturers were kept busy, yielding fair profits to them and good wages to our workingmen. It is quite different uow. With cheap and quick transportation the Eastern manufacturers, whose material and labor cost less, can pour their goods into this city, over the entire coast and into the interior of the State. The extra cost of the material from the East is fully offset hy the freight on the manufactured article.

Our climatic conditions and other minor advantages are in our favor, though not enough to offset the less cost of Eastern labor, proof of which is to be seen in the warehouses of our importers and on the sidewalks in front of their premises.

If any one will go into our large establishments using machinery, including engines, boilers, etc., he will find that nearly all are of Eastern manufacture.

The other day we happened into an establishment using five Corliss engines. We found one of California manufacture, built several years ago. All the others were built East. The boilers were all of Eastern manufacture. The machinery of that establishment would have kept a shop of fair size running six months in the building of their machinery. The Electric Light Company of this city has one or two engines that were built here, hut all the engines put in during the last few years are of Eastern manufacture and of such magnitude that they would keep one of our large shops running for one year without other work. There is much more machinery of Eastern manufacture sold here than would keep our shops busy the whole year round, giving steady, instead of occasional, employment, aiding our industrial population and retaining the money on the coast that is now sent East, instead of which our work-shops are reduced to the condition of jobhing shops, picking up the crumbs left after the Eastern manufacturers have had their fill. The question of greatest importance in the discussion of this subject is that of labor. In the manufacture of any article all engaged in it ought to have an equal share. The raw material demands so much. The artisan or other workingman should have his share and the manufacturer his, as well as a reasonable interest on the money invested. With these properly adjusted there should then he no hindrance to our manufacturing prosperity and the welfare of all engaged in it.

Do we wish to manufacture for our requirements or would we rather send away our money to obtain the manufactured article from the East? If we wish to manufacture we will have to do so at a price to meet that of the East, with freight added, and the question is, How are we to bring this about?

As already stated, the material and merchandise purchased for manufacturing costs so much; the balance is labor and the manufacturer's profit. These last two items should be equitably divided, so that the laborer will receive his share and the manufacturer his. If the manufacturer claims too much, then the laborer unjustly suffers. On the other hand, if the laborer claims too much, the manufacturer cannot go on and business will suffer; but if equitably divided then both will succeed. At the present time it is impossible to compete with the East in building a large class of machinery now brought here, and until such a time as labor is brought approximately to an equality with that of the East efforts in that direction will be unsuccessful.

Could we protect ourselves against the East by a tariff, the discussion of this question would be unnecessary. This is a question on which the manufacturers dislike to publicly express themselves, and it is done here with all due respect to the workingman. It would please us just as much, if not more, to have the wages paid to the workingmen in the East raised rather than have the same reduced here, but if we are to succeed an equality, or nearly so, is essential. If such a condition should he brought about so that mechanics would have constant instead of occasional employment, they would, on the average for the whole year, earn more at a lower rate of wages than they have done in the past at a greater. Such a condition would also bring about a cheaper price for the commodities of life, including rent, fuel, etc. The cost of living to the workingman is very important. With tbe exception of rent and fuel living is as cheap here, and in the case of many articles, cheaper than in the East. Rents within the last few years have been considerably reduced, and we do not think it will he a long time before they will be as low here as anywhere in the United States. Fuel, for some time to come, we think will remain higher, hut less is required on account of warmer winters. With the condition of less cost our workshops can take up specialities instead of doing a little of everything in the line of mechanics, which will be a great relief to their management. At the present time as much hrain work is required in conducting one of our shops as is needed in half a dozen of those in the East where they make specialties.

To relieve the severe strain upon the employer, with reasonable compensation for his labor—to give constant employment to the workingman at a rate of wages which would he just—I think tbat if representatives of each would come together and discuss the subject with their mutual interests in view, that the question could be settled profitably and satisfactorily to all interested and enable California, instead of pouring out her vitality in coin sent to others to supply her wants, to huild up her own industries hy her own hands.

Utilization of Water Powers.

Abstract of a paper read beforo the Manufacturers' Convention, last Wednesday, by A. P. BRAYTON, President of the Pelton Water Wheel Company.

There is no subject so vital to tbe manufacturiug interests of the country as cheap power. It is the one thing absolutely essential to success in any enterprise of this character. The great industrial centers of the world are all located either in close proximity to a water power or where cheap coal is available.

Manufacturing in this State, it is well known, has been carried on at a great disadvantage on account of the high cost of coal, a condition which, after the lapse of more than forty years, has not materially improved, and there is still hut little to hope for in this direction. It is evident, therefore, that some other resource must be had for cheap power, to afford encouragement to our manufacturing interests.

The Pacific coast has a magnificent endowment in its bounteous water supply and under conditions most favorable for its development. Innumerable streams are coursing their way down the mountains, carrying sufficient power, if properly utilized, for every industrial enterprise now existing or likely to be developed during the next half century. This immeasureably vast resource has not heretofore been availed of to any considerable extent—except for mining purposes—on account of its remoteness from desirable points for carrying on manufacturing operations.

The wonderful progress recently made in electric power transmission makes it possible now to avail of water power a distance of fifty miles or more from the source of energy, with comparatively small loss and with all the reliability of the most modern steam appliances. The prediction is made by some of our most conservative electricians that the power of Niagara falls will at no distant day be carried to New York City and Chicago, involving in either case a distance of some 500 miles, and successfully compete with the cheap coal obtainable in these localities. Long before power transmission such a distance may be deemed practicable, the waters of Lake Tahoe and various streams from the Sierras may be made available for power purposes in San Francisco and other cities of the coast.

Even cbeap fuel cannot compete with water power, though electrically transmitted a very considerable distance. This is evidenced from the fact that power transmitted from Niagara falls to Buffalo, twenty miles distant, is expected to compete witb steam produced from coal costing not more than $1.25 per ton and this with a plant involving an outlay of upward of $4,000,000.

The relief sought for, not only in this State, hut in many other localities, is to be found in making these vast sources of energy available for manufacturing and mining purposes to a much larger extent than heretofore and the time is now ripe for enterprises in this direction. There are many accessible points that can he supplied with power so produced, involving a comparatively short transmission, which would soon grow into important manufacturing centers.

To indicate the progress already made in this way, as well as the fact that such means of power are in no sense an experiment, it may he stated that there are now not less than sixty electric transmission plants in operation west of the Missouri river, run by water power, some of large capacity, and every one, so far as is known, has been a most pronounced success, both from an engineering and financial standpoint. A brief reference to some of these may be of interest in this connection.

A 500-H. P. plant, costing about $40,000, was installed on a mine in the Cœur d'Alene district, Idaho, two years ago, and the superintendent reports that the entire cost was saved in the first year's run. In a plant of similar capacity at Ouray, Colorado, involving a cost of some $50,000, a saving of $40,000 a year is claimed over the cost of operating a steam plant. On the plant of the Standard Mining Company at Bodie, in this State, involving a transmission of thirteen miles and an expenditure of $38,000, a saving of $2000 per month is reported by the superintendent. A 2000-H. P. plant, to be operated under 800 feet head, involving a transmission of twenty-three miles and costing $300,000, is now under construction near the City of Mexico, the dividends on which, as claimed by the investors, will return the entire outlay in two year's time.

While these references are somewhat exceptional as to returns, it is a fact beyond question that installations of this character have been in the main extraordinarily remunerative, a large number having paid from twenty-five to forty per cent per annum on the investment.

Power stations, well planned with reference to water supply, distribution and the wants of consumers, afford a safe and profitable outlet for much of the idle capital accumulating in the financial centers of the country. With all the inducements offered, there has, however, been a lack of confidence on the part of capitalists in enterprises of this character, and many projects involving the utilization of water power in various localities, some of great promise and importance in an industrial sense, are languishing for want of financial support. It is to be hoped that such investments may in the future find more favor, especially as they are so intimately connected with the general welfare and prosperity of the community.

In the South it used to be said that "Cotton is King." With us Water is King, as it will not only fertilize all the barren plains, but if harnessed to work, will turn every wheel of industry.

Ore Sorting in Colorado.

The following, by W. A. Bray, is from the Victor *News*: Ore sorting, in a large percentage of mining operations, is one of the most important departments of the work As the ore and the rock come out of the ground they are dumped in the sorting-house, for that purpose.

Each person has a heavy iron casting—a worn stamp-shoe—on which he breaks the ore. The sorting hammer is shaped something like the hammer used by stonecutters, and is made especially for the work. The operation of sorting consists of separating from the waste the ore which is rich enough to pay, or the low-grade ore which is too poor to pay for shipment to the smelters or reduction works for treatment.

The good ore is separated from the waste by clipping off the poor portions of rock from the good, or vice versa. It requires a good deal of skill, in most cases, to break the pieces of ore and rock in such a way so that they can be easily separated without wasting much ore. Sorting is a trade; it is more difficult according to the character of the ore. In some cases the ore occurs in such compact streaks that it is easily separated from the waste, one man being able to sort several tons per day. In these instances the ore, after sorting, will be in pieces ranging in weight from two or three ounces to several pounds. At other times the ore may be in thin streaks, in a great deal of waste, and will require great care in sorting. In these, after sorting, it will be in pieces as large as a walnut. In some cases ore sorters can sort as much ore as ten miners can break in the mine and send to the surface; in other cases it may require half a dozen sorters to dispose of what one miner can break.

The question of sorting is one that cuts a very important figure in the profit-and-loss account of many mines. It is quite evident that the expense of preparing the ore for the market will be a great deal more per ton in the mine where six sorters are required for each miner than where it will be if there is only one sorter for ten miners. This is one of the items in mining accounts for which the great majority of our Eastern friends pay very dearly in learning.

It is very seldom that a mine produces ore so free from waste rock, and in such quantities that it can be waste, that it will not require sorting. Mines of this character, broken or mined separately, are generally those carrying large bodies of low-grade ores. Rich ore generally occurs in small quantities, scattered through a great deal of gangue.

Quartz vs. Placer.

From the early days of Sierra county to this late day most of the energy of the prospector and the money of the capitalist was devoted to the exploration and development of placers.

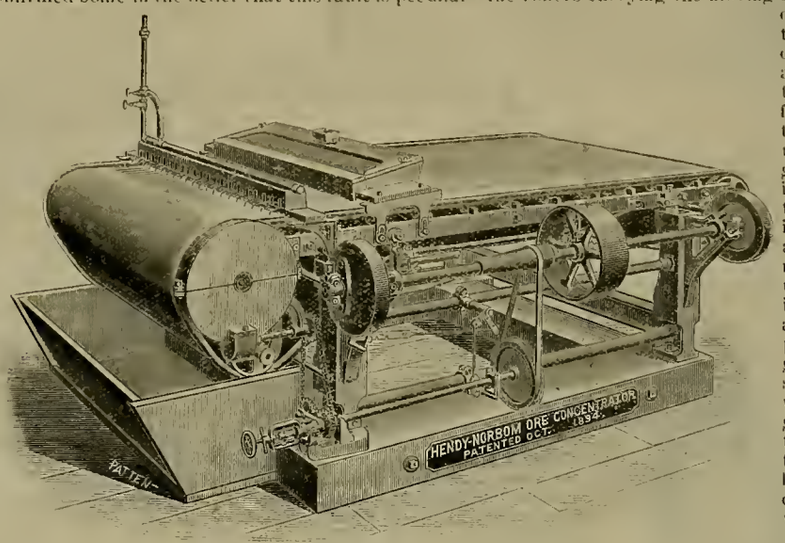
In the very early days this was an easy matter, for the reason that the beds of the rivers, creeks and ravines—their banks and the shallow benches above—were rich in gold, so that from an ounce to a tincupful of gold per day was the ordinary miner's luck; but those days quickly passed and a search for the deep placers was commenced, when, by an aggregation of large numbers of comparatively poor men, many of the deep mines were found, and the Monte Cristo, Fir Cap, Bald Mountain, Old Union, Empire and many other drift mines were then opened, some of which are at work to-day. Later on the assistance of the capitalist was called in, and, by the aid of corporations, the Thistle Shaft, Bonanza, Bald Mountain Extension, Ruby and others were developed and their stream of gold was turned into the channels of trade. Most of this time the impression seemed to prevail that Sierra county was essentially a placer county; that, although it had quartz in abundance, it was supposed to be like the early placers, shallow, or, to use the miner's expression, "It didn't go down," and, as a consequence, comparatively little of the prospecting has been devoted to quartz. On this theory numbers of quartz mines have been worked only as long as the ore could be dropped to the mill, and as soon as it became necessary to sink they were shut down, and a failure in a few instances to find a pay chute of ore on a lower level has almost confirmed some in the belief that this fault is peculiar to our quartz mines; but a moment's consideration of the matter will satisfy any one that it is an assumption based upon the exception and not upon the rule, and the exceptions are taken from the mines where the lowest tunnel still drains them—where no sinking below water level has been made. On the other hand, the Gold Bluff, the Alaska, the Independence, the Marguerite (now called the Tecumseh), the Brush Creek and all of the mines that have been sunk below water level have maintained a uniform richness of ore to the bottom of the shaft, and in every instance where any of these mines have shut down, the cause has not been for lack of pay ore in the bottom, but for inadequate machinery to handle the hoists and pumps.

We therefore contend that everything points to the fact that our mines do go down, and we believe that much of the prosperity of our county depends upon the development of our quartz mines.

"One swallow does not make a summer," nor does the fact that an occasional mine has a barren spot in it make all the mines worthless. The far-famed Kennedy mine, now down over 1500 feet and yielding immensely, was once abandoned because they said it didn't go down, caused by striking a barren spot in it, but after sinking through the barren spot the ore was richer than ever.—Downieville Messenger.

The Hendy-Norbom Concentrator.

The machine herewith illustrated belongs to the class of concentrators in which an endless belt, moving slowly uphill, discharges the concentrated sulphurets over the head or highest end and the tailings run down the belt and discharge at the tail or lower end. It has been customary to give to this class of concentrators or vanners a shaking or percussion motion, caused either by eccentries or cranks operated on a revolving shaft placed either on the side or in front of the shaking frame on which the rollers carrying the moving belt rest. The principle upon which these machines concentrate is by giving a percussion motion to the belt-carrying frame to cause a settling of the sulphurets owing to their greater specific gravity. In places where the free gold occurs in a very fine state and fine crushing is necessary, sliming is unavoidable, and it is very often deemed advisable to sacrifice part of the fine free gold by using coarser screens, the cause of which is that the fine gold will get lost in the coarse sands, but the sulphurets will be in better state for concentration on the vanners.



THE HENDY-NORBOM CONCENTRATOR.

The machine can be converted into a side-shaking vanner by removing the curved springs and inserting the straight legs in their places, by lengthening the strokes of the adjustable eccentrics, speeding up the machine and putting on a rubber belt. By keeping a straight leg and a curved spring on each side of the machine a panning motion will be obtained, the inventors having thought it advisable to build a machine that could be given different motions and that would work on different principles, in order to enable millmen to experiment and find out what motion is most suitable for their particular class of ore.

The inventor and manufacturers say the machine is simple in construction, requires very little attention and is substantial and durable. The 50-stamp mill on the Grand Victory mine, near Placerville, has recently been equipped with this class of concentrators. They are also working successfully in Grass Valley, and some machines were lately sent to the Bald Eagle mine in Alaska.

The machine is the invention of John Norbom and is manufactured by the Joshua Hendy Machine Works in this city.

Water.

Pure water consists of two parts hydrogen and one part oxygen. Chemical name hydrogeu oxide, chemical symbol H_2O. Pure water is a colorless, odorless, tasteless, transparent liquid, and is practically incompressible. Water freezes at 32° F. and boils at 212° F. At its maximum density—39.1° F.—it is the standard for specific gravities, and one cubic centimeter weighs one gramme.

1 U. S. gallon = { 231 cubic inches. / 0.13369 cubic foot. / 8.3311 pounds distilled water. / 8.34 pounds—in ordinary practice.

1 cubic foot = { 62.425 lbs at 39.1° F., max'm density. / 62.418 lbs at 32° F., freezing point. / 62.355 lbs at 62° F., standard temp. / 59 64 lbs. at 212° F., boiling point. / 57.5 lbs. at ice.

1 cubic foot.. = 7.485 U. S. gallons.
1 pound..... = 27.7 cubic inches.
1 cubic inch.. = 0.03612 pound.

A columu of water one iuch square and 2.31 feet high weighs one pound.

A column of watcr one inch square and oue foot high weighs 0.433 pound.

A column of water 33.947 feet high equals the pressure of the atmospherc at the sea level.

One pouud per square inch equals a column of water 2.31 feet in height.

0.433 pound per square inch equals a column of water oue foot iu height.

Water is an almost uuiversal solveut, consequently pure water does not occur in nature. Sea water contains nearly every known substance in solution.

The latent heat of water is 79 thermal uuits. When water freezes it gives off its latent heat. The latent heat of steam is 536 thermal uuits. When steam condenses into water it gives off its latent heat.

An Important Event.

On the 20th of next Juue the canal between the Baltic and North sea will be opened by Emperor William iu the presence of the highest dignitaries of Germany and representatives of other countries. The principal nations will also be represented by meu-of-war. It is expected that the pomp and ceremony will rival the scene at the opeuing of thc Suez canal. Thc Hamburg-American line will join in the naval parade with two of their twin-screw express steamers, the Augusta Victoria aud the Normaunia. A few data in reference to the canal will illustrate the importance of the work. It starts at Keil, on the Baltic sea, and, crossing the Prussian province of Holstein, joins the Elbe at Brunsbuttel, below Hamburg. Work was begun on June 3, 1887, and over 8600 men were employed during the summer months, whilc in winter the number was reduced to about 4700. The plant comprised 90 locomotives, 2473 cars, 66 dredgers, 133 lighters and 55 engines. The estimated cost was 156,000,000 marks ($37,440,000), and the thoroughness of preparatiou and efficiency of execution canuot be better illustrated than by mentioning the faet that the estimate has not beeu exceeded. There will be two locks, one at the Baltic end, opeu all the year round except twenty-five days, and one ou the Elbe, open three to four hours during every flood tide, so that it may almost be termed a tide-water canal. Its length is 53½ miles; average depth, 29½ feet; width at bottom, 72 feet; width at water level, 213 feet. At Brunsbuttel, on the Elbe, there is an outer harbor, 1312 feet long by 328 feet wide; then follows the lock, 492×82 feet, aud 32⅘ fcet deep, aud then an inner harbor, 1640 feet by 656 feet. Two fine suspension bridges cross the canal uearly 138 feet above the water level, so that railway traffic will not be interrupted. The speed allowed ou the canal will be 5.3 miles an hour, makiug the time of passage about thirteen hours. The toll will be seventy-five pfenniugs, or eighteen ceuts, a uet register ton (loading capacity). It is expected that about 18,000 ships will make use of the canal annually, representing about 7,500,000 tons. Hitherto about 35,000 ships have passed every year through the Skager Rack and the Cattegat, between the Baltic and the North sea, so that the estimated percentage seems fair. Thc saving of time will be cousiderable, since for all ships bound to or from any point south of Hull the distance will be reduced by 238 miles. Bremeu ships will save 322 miles, and Hamburg ships 424 miles. But more important than the saving in time is the avoidance of danger, the passage through the sound betweeu the Scandinavian peninsula and Jutland being considered one of the most dangerous in Europe. Statistics show that about 200 vessels founder every year on these coasts. The strategic value of the canal is, besides, of the greatest value to Germauy, becausc its men-of-war will uow be able to pass from the North sea to the Baltic with ease and safety, avoiding the passage through foreign waters, and permitting rapid concentration on the north or the west coast.

THE year 1900 will not be a leap year. Every year is a leap year that is divisible by four, exceptiug those ending iu two cyphers, which must be divisible by 400; thus, 1600 and 2000 are leap years, but 1800 and 1900 are not. Julius Cæsar reformed the calendar by makiug three years of 365 days each follow one year of 366 days, or, in short, every fourth year was made a leap year. This calculation gives an error of about eleven minutes too much each year, which has aggregated uow nearly twelve days. In order to obviate this error Pope Gregory, in 1582, declared October 5th to be October 15th, and made the rule that thereafter century years not multiples of 400 should not be leap years. The Gregorian calendar has been adopted in all civilized countries save Russia. This system of intercalculation recouciles with much accuracy the civil and solar years. The latter contaius 365 days, 5 hours, 48 minutes, 49.62 seconds. By omitting three leap years cvery 400 years it gives the civil year an average duration of 365 days, 5 hours, 49 minutes, 12 secouds, which exceeds the true solar year by 22.38 seconds, amouuting to a day in 3866 years.

Selby Smelting and Lead Company,
416 Montgomery Street, San Francisco.

Gold and Silver Refinery
—AND—
Assay Office.

HIGHEST PRICES PAID FOR GOLD, SILVER AND LEAD ORES AND SULPHURETS.

Manufacturers of

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—GOLD AND SILVER ORES.

SECOND EDITION—PRICE $1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes wherof he knowe from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake its meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:—Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12-mo pages, with illustrations, well bound in cloth; 1889. Price $1.00 postpaid. Sold by the Mining and Scientific Press, 220 Market St., San Francisco.

Parts II and III.—Gold and Silver Bullion, Lead, Copper, Tin, Etc.

SECOND EDITION—PRICE $1.75.

This book is entitled "Assaying—Parts II and III," and is separate from part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickle, Cobalt, etc.

Table of Contents:—Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickle and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc.

The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, $1.75. Sold by the Mining and Scientific Press, 220 Market St., San Francisco.

HEALD'S

Business College,
24 Post Street, - San Francisco.

FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. ☞ Extra sizes and lengths made to order on short notice

611 and 613 FRONT ST., San Francisco, Cal.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Mechanical Progress.

Fire Tube and Water Tube Boilers.

In the "Scotch" type of marine boiler, long a great favorite among constructors of vessels for merchant and naval service, the fire passes through the tubes or flues as in a locomotive boiler, and the water surrounds them, being itself contained in a larger shell. But in the "water tube" boiler the fire is on the outside and the fluid within. Regarding the advantages of the latter class of steam generators for use on land or for small craft like yachts and torpedo boats, there is no great difference of opinion. To the introduction of such boilers to big steamships, however, certain objections have been offered; and, as their validity is not universally conceded, there have been some rather warm disputes on this subject among engineering experts during the last three or four years. For the water-tube system it is claimed that, for the same amount of power developed (1) less metal is required; (2) less water needed, both of which features reduce the space and weight; (3) steam can be produced more quickly; (4) the water is more evenly heated; (5) higher pressures may be carried (250 pounds to the inch, say, instead of 150 or 180); (6) repairs are more easily made, and (7) that in case a vessel so equipped is penetrated by a shot from a warship, a less destructive explosion occurs. On the other hand, it is urged that (1) the vaporizing action occurs in a more confined space; (2) the metal surface is not so well protected against the destructive action of the flames; (3) steam is not developed so rapidly with a given heating surface; (4) more fuel is required; (5) the boiler is shorter lived, and (6) that the automatic feed requires extra attention.

This wide difference of opinion imparts interest to the announcement that a Chicago shipbuilding concern is about to make a competitive test of both classes. Two large freight vessels, intended for duty on the lakes, are under construction after exactly the same designs, except that one will have fire-tube and the other water-tube boilers. Engineer-in-Chief Melville, of the United States Navy, has agreed to supervise the experiment, which affords reason for believing that it will be intelligently and fairly conducted. The results will not be decisive of the whole question, to be sure, but they may shed some light on it at any rate.

Iron Cheaper in the United States Than England.

The London *Iron and Coal Trades Review* says: "It is some considerable time since we pointed out that the threat of successful competition in neutral markets on the part of the United States was not a mere 'bogey,' but was likely in course of time to become a stern reality. We have good reason to know that the reality now comes nearer every day. The paper which was read a few days ago before the Middlesborough Chamber of Commerce by Mr. Jeremiah Head pointed in unmistakable terms to the coming supremacy of the United States in the manufacture of pig iron. It was shown conclusively by Mr. Head that in Alabama pig iron is produced and sold for about five shillings per ton less than it costs in Cleveland, the cheapest center of the pig iron industry in this country. It is true that we have not as yet been flooded with this cheap American pig in European markets, but it is not at all improbable that this event will happen by and by. The drawback to the success of the Alabama pig-iron makers at the present time is the comparatively high cost of transport. Situated nearly 300 miles from the sea, and a still longer distance from the great shipping ports, the Birmingham district of Alabama cannot place its produce in many American markets—not to speak of the markets of Europe—for anything like the price at which Cleveland pig can be supplied at home. Whether land and ocean transport will, in the future, be reduced sufficiently to enable a change to be made from this point of view is, of course, an unsolved problem, but the margin of five shillings now in favor of Alabama pig must be increased considerably before we need fear the advent of that product on British soil to any extent worth speaking of. Meanwhile, however, certain other branches of the iron and steel industry have been successfully attacked by our American rivals, under conditions and with an amount of success that may well cause us a good deal of disquietude. We have the most ample evidence of the fact that the cost of steel billets at the works in Pittsburg is cheaper than at works in Glasgow or Sheffield. In other words, the cost of making billets in the United States has been brought down to about 18s 6d per ton, and in some cases perhaps a trifle less, whereas we are not aware of any works in Great Britain where the cost has been brought down under 25s per ton, although, of course, it is possible that it may have been done for something under that figure. That this should have happened in a country where the rate of wages paid is understood to be twenty-five to thirty per cent more than our own is one of those economic problems that are exceedingly difficult of solution. But the effect of the fact is that the American wire manufacturers are making havoc with our English wire trade in Central and South America, and are doing considerable business in Canada."

Photography Under the Sea.

The stupendous progress of maritime science during the last decade made reliable illustrations of objects under water very desirable, and to obtain such pictures photography was, of course, resorted to. It was by no means an easy matter, but with the apparatus herein described the problem appears to have been successfully solved. An ordinary magazine camera, of small size, and adjustable to focus at various distances, is inclosed in a water-tight metallic case, which is furnished with plate-glass lights on each side. Two buttons on the outside of the metallic case work respectively the shutter and the mechanism for focusing. Where the metallic case is pierced a layer of compressed oakum prevents moisture from entering. A metallic tripod of sufficient weight to insure stability completes the outfit. The photographic plates used for this purpose are specially prepared, and are considerably more sensitive than ordinary dry-plates. For certain contingencies a lighting apparatus has been constructed, which for ingenuity rivals the camera. An ordinary magnesium flashlight lamp is fastened to the top of a barrel of about fifty gallons capacity which is weighted down with shot, and also serves as a reservoir for the air supply of the lamp. This lamp is protected by a glass globe, which is fastened hermetically over lamp and spigot, and is also used as a reflector. A rubber bulb containing the magnesium powder and a rubber tube leading to the pointed metal tube in the flash-lamp furnish the means to produce a flashlight by simply pressing the bulb.

The timing of the exposures presents another serious difficulty. At a depth of three to four feet an exposure of ten minutes will give good results; at a depth of fifteen to eighteen feet the exposure should last not less than thirty minutes when the sun is brightest. Even at this depth it becomes necessary to apply a plate of blue glass in front of the lens in order to obtain clear pictures. In deeper regions photography would be impossible but for the flashlight apparatus described above. It saves time and trouble, and good pictures have been taken even during storms and without appreciable light from above.

Wire Silver Produced by Artificial Means.

Professor Phillips, of Alleghany, Pa., is reported to have recently succeeded in obtaining wire silver by artifice. Hitherto wire silver has been known only in nature, and all attempts to reproduce it in the laboratory have failed.

In nature the white metal is found in the form of wire silver, so called because of its peculiar appearance, somewhat resembling fine wire tangled together. Often it looks like moss. Considerable masses of it are sometimes discovered, the minerals with which it was associated having been dissolved out and washed away. Frequently such chunks have been termed nuggets, but there is no such thing as a real nugget of silver.

Silver is exceedingly ready to combine with many other elements, such as arsenic and sulphur. Most commonly it is found associated with the latter, taking the form of a sulphide. Its affinity for sulphur is illustrated by the fact that it quickly becomes much tarnished if exposed in the same room with the contents of a stale egg, the decomposition of which sets free sulphuretted hydrogen.

By Professor Phillip's experiments, he makes wire silver artificially by treating a nitrate of the metal with hydrogen gas.

It may easily be imagined how wire silver produced by artifice might be employed to deceive. The production of wire silver by artificial means is interesting only as a laboratory experiment. No commercial use for it has been suggested as yet.

Money Value of Hands and Fingers.

According to a scale drawn up for the Miners' Union and Miners' Accident Insurance Companies of Germany, the loss of both hands is valued at 100 per cent, or the whole ability to earn a living. Losing the right hand depreciates the value of an individual as a worker 70 to 80 per cent, while the loss of the left hand represents from 60 to 70 per cent of the earnings of both hands. The thumb is reckoned to be worth from 20 to 30 per cent of the earnings. The first finger of the right hand is valued at from 14 to 18 per cent, that of the left hand at from 8 to 13.5 per cent. The middle finger is worth from 10 to 16 per cent. The third finger is valued at no more than 7 to 9 per cent. The little finger is worth 9 to 12 per cent. The difference in the percentages is occasioned by the difference with the trade, the first finger being, for instance, more valuable to a writer than to a digger.

In a recent meeting in England, Alexander Siemens gave some wholesome advice to young engineers and inventors. He dispelled the fable about the circumstances which led to the invention of the steam engine. According to the popular version, Watt, as a small boy, saw the lid of a kettle move up and down when the water was boiling, and this suggested to him the construction of the steam engine. As a matter of fact, Watt made himself acquainted with what had been done before (a point altogether ignored in the popular version), and had to work very hard before he brought his invention to a successful issue. His example is typical of the true method of progress, and it may be said, generally, that, in order to approach a problem with the best prospect of success it is necessary (1) to define as accurately as possible the want that exists, or the particular object to be attained; (2) to be well acquainted with the scientific principles which come into play; (3) to know the want is met, or the object attained in practical life; (4) to find out what proposals have been made by others in the same or in a similar case. A careful attention to these requirements will prevent much disappointment and waste of energy.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AROUND OLETA.—In the vicinity of Oleta gravel and quartz mines are employing ablebodied man.

The principal mine being worked is the Lone Hill. The Davis and J. H. Hill mines are also being successfully operated, the former employing twenty men. All these mines are working channel gravel, similar to the famous "blue lead," and quite as rich. It is not an infrequent thing to turn in gravel carrying from $4 to $5 to the car.

The extent of the lead is not even bounded by section lines, and will furnish work for a generation or two of miners.

The Lone Hill has a fine mill run by hydraulic pressure. The machinery is of the most modern pattern, and has not only a large capacity, but saves every particle of gold. The company has leased the Perrington ditch, lately purchased by D. R. Thomas, and has in this way secured control of the entire water supply.

Eight miles above Oleta the Robertson brothers have struck an eighty foot ledge of porphyry and quartz carrying low-grade ore. It runs from $3 to $4 to the ton, and the proprietors have such faith in the property that they will construct a twenty-stamp mill.

Another new mine is that located by Henry Linton, and known as the Coffey Gulch mine. This lead, while small, produces rock running as high as $1,500 per ton. The mine has not yet been thoroughly prospected, and sinking, it is hoped, will develop a large ledge.

D. R. Thomas, superintendent of the Hill Top mine, now the property of the Interior Development Company of San Francisco, is expecting to commence the construction of one of the largest reservoirs in the State on the old Case ranch at the head of the South Fork of the Consumnes river.

The purchase of the site was made some time ago, but immediate work deferred pending the adjudication of litigation involving large interests in the western part of the county. This reservoir will be the first of a system which will add thousands of inches of water to the old Perrington right, now the property of Mr. Thomas.

Butte.

THE MASCOT.—D. & F. Wyckoff have bonded the Mascot quartz mine at Oregon City and will develop it.

El Dorado.

STANDARD M. CO.—*Democrat:* The Standard Mining Company at Pleasant Valley have their shaft down 130 feet, where they struck bedrock pitching to the south abruptly. In order to get the deep channel they are running south 100 feet, at end of which they will sink a shaft, hoping there to strike the deep channel, where they may reasonably expect to find a bed of rich gravel. This belief is justified by the fact that the surface along the sides of this channel has been worked since early days and paid very rich. Only a few hundred yards from the Standard shaft Mr. John Fink sunk a shaft for the purpose of getting water, and at a depth of twenty-four feet struck a bed of rich gravel ranging in thickness from 2½ to 5 feet. This find of Mr. Fink's is evidently a bench running parallel with the main deep channel. Good prospects are being found on the Volshurg claim, about one mile southwest, and still farther on the same line is the Stevens and McKinney claim, which has been worked to some extent on the vein the present winter, yielding coarse gold in paying quantities, evidently an overflow from the main channel.

Fresno.

A VERITABLE GOLD POOL.—At the confluence of Fine Gold Gulch creek and the San Joaquin there is a deep pool which has one of the largest mining camps on the river located on its banks, though not an ounce of gold is being worked. A dam is being built 200 feet above the mouth of Fine Gold Gulch, and a canal 700 feet long is being cut, through which the waters of the San Joaquin are to be diverted. As soon as the waters of the river are turned the outlet of Fine Gold Gulch will be turned also. It is believed that the whole of the engineering work can be completed by June, and the pumps will clear the pool in which considerable gold is expected to be found.

That there is gold in the pool has been proved by well borings sunk at different spots. The average depth of the sedimentary deposit above the hard bedrock of the river is from five to seven feet.

Nevada.

MINE TO START UP.—*Union:* The Morning Star mine on Gold Flat will be started up about the first of April. A San Francisco company, who bought the mine some time ago, will erect hoisting works and fully develop the property. Mr. Sine of San Francisco will have charge of the mine. The shaft is down about 100 feet, but the company will sink a new one. The ledge is from one to two feet wide and the rock paid $50 and $60 per ton.

A GOOD LEDGE.—*Herald:* In the Blue Jay mine, at Maybert, an eight-foot ledge has been developed, and the rock is of a good quality. Pay rock is being taken out, and the mill will be started when the ditch supplying water is open. The Blue Jay is an example of what may be done by experienced miners, when the strictest economy is practiced. A five-stamp mill, running less than one-fourth of the time for the past year and a half, has paid for itself and the mine and left something for the owners. A twenty-stamp mill and extensive buildings would have swamped the entire business. There are plenty of places where the same system would work equally as well.

THE CENTENNIAL.—The gravel in the Centennial mine, up the Washington ridge, continues to pay, and it may he that the company is to get back the large sums of money they have spent there.

THE BULLION.—Is is expected that the Bullion property, comprising the lone and Galena, at the base of Osborn Hill, on the Colfax road, two miles from Grass Valley, will have work resumed shortly under the superintendency of Geo. Mainhart.

WHITE HORSE DISTRICT.

The Sunset mine continues idle, no work being done in the shaft this spring.

Senor Ortega has succeeded in raising $4000 to build a mill on the Addie C mine.

The Emma L has not advanced any, as the water from melting snow has been had in the tunnel. The Emma L company expect to rebuild and start their arrastra soon.

The J. G. Blaine continues to be the largest operating mine in the district. A drift is being run south now from the first station in the east drift. It is the intention to run 100 feet in that drift, and timbers are being made ready for that purpose. The superintendent has shown some rock that will assay $100 per ton.

Plumas.

THE THISTLE MINE.—*Independent:* The Thistle drift mine now employs 100 men and is a good gold prodneer.

QUINCY MINING AND WATER CO.—*National Bulletin:* Supt. A. B. White arrived from helow last week, via Reno, and proceeded to Spanish Ranch. Foreman Campbell, for several weeks past, had been getting things in readiness for active operations. During the past few days Mr. White has been employing more men for the purpose of getting the water started through the ditches and into the pipes. The washing of gravel will begin as soon as this work is accomplished, and will continue through the entire water season, which promises to be a very lengthy one—unusually so in consequence of the immeuse banks of snow lying around the base of Spanish Peak, which is drained by the large water system of the Quincy Mining and Water Co. The operations of this company will furnisb employment for quite a crew of men during the spring and summer. The area of gravel deposits is very large, and from those worked in years gone by very large sums of gold were taken. It is believed that fortunes remain in the unworked gravels of the ancient river channels which thread the territory owned by the company. The corporation is well equipped for successful mining. It has one of the most extensive and effective water systems to be found in this part of the State, and on its own lands is plenty of timber for all purposes pertaining to the mine, and should it ever desire to engage in that line of busines, it will be ahle, with its facilities of developing water or electric power, to convert into lumber the large forest of valuable timber on the slope, extending from the base of Spanish Peak dowu to points north of Quincy. On the arrival of the railroad, which has already been partially built into Plumas and which will he extended this spring and summer, lumber could he shipped to profitable markets.

GULLIC & COMPANY. — B. F. Gullic is expected to return from Illinois to Greenville, this county, in a short time, accompanied by his family. He will at once proceed in the work of erecting a 20-stamp quartz mill on the Hibernia properties, near Greenville; on which his compauy did much development work last fall, the results being very satisfactory. It is probable that, on this property, thirty or forty men will be emyloyed during the coming season. The Hibernia and adjoining mines, owned by Gullic & Co., are south of Greenville and in the mountain so fruitful of gold-hearing quartz veins. That they have a valuable property, the owners have no doubt. They made a milling test of the ore last fall and the yield proved so satisfactory that a purchase of the property was made and the improvements referred to determined upon.

THE BUTTERFLY MINE.—The Butterfly mine is now being operated under the management of Prof. C. D. Kellogg, who last fall interested Eastern capital. A ten-stamp mill has just been completed and the crushing of ore has begun. In the work of preparation the management has had a severe winter to contend with, but much pluck and energy have been manifested, and now the wheels are rolling.

McGill and Standart will resume work on their mine near Greenville as soon as the absence of snow will permit.

The Trelcaven brothers are expected to open up the old New York mine at Greenville in the near future. It is a property which has produced considerable money.

B. F. Leete, of Reno, Nevada, expects to do considerable development work on his quartz mine near Cresecent during the coming season.

Work on the Lucky S. mine has been resumed, but only a small force will be employed until the conditions of weather favorable to work have arrived.

The indications are that Granite Basin will be a lively mining camp this year.

The Pioneer mine at Grass Flat, near Port Wine, will soon have a large force of men employed.

Siskiyou.

HAWKINSVILLE AND YREKA.—Mining operations at Hawkinsville this spring and summer will make Hawkinsville and Yreka lively. In Yreka not a dwelling house can be procured for rent, many persons being obliged to buy, while others in want of residences intend building.

The thirty-ton pump for raising water from the electric light ditch at Shasta river, to work mines at Hawkinsville, is at Yreka, on its way down to the river via the Hawkins road. It will force water to a hight of nearly 500 feet through 1100 feet of large pipe, in supplying a dich for working the diggings near Hawkinsville in the Yreka basin.

GENERAL MINING NOTES.—*Journal:* Work has been progressing all winter in the cinnabar mines on West Beaver Creek, Siskiyou mountain, by tunneling. When the snow disappears the ore will he retorted.

The Spangler Bros., at mouth of Humhug creek, have succeeded in getting their diggings pumped out, by having a pump some distance above their pit on the creek, and another at the pit, so as to permit hoisting pay gravel.

The McConnell and Pacific river claims in the Klamath, just helow the mouth of Humbug, are to he worked on an extensive scale this season. A long wingdam is to be built for covering both claims, which are adjoining on an island, and will be pumped out under the superintendence of Marsena Mott.

Brown & Hossick have struck a high-grade ochre quartz mine on the middle fork of Humhug, about ten miles from Yreka, which prospects over $35 per ton. The ledge is about five feet in width, and there is an abundance of good paying quartz in sight, to be crushed shortly in McCook's mill at the forks of Humhug.

Clark & Callick have fifty tons of quartz already taken out of their ledge on Old Craggy mountain at Humhug, the rock being of a milk-white character, and yielded at last crushing an average of $21 per ton.

Coulson & Lash have a good ledge on the midddle fork of Humbug, with considerable rich ore in sight.

Elliott Creek, up in the Siskiyou, close to the Oregon line, seems to be a rich placer mining district, as several claims have been lately taken up there, near the headwaters of Cettonwood creek.

The Eastliek Bros., says the Scott Valley *News*, started up work in their hydraulic mine at Oro Fino last Friday. The electric lights recently put in did not work satisfactorily, and the old-fashioned torch is being used while the e'ectric plant is being overhauled and corrected.

Sierra.

GENERAL ITEMS.— The Ruby mine is at present employing eighteen men, and is not on a paying basis. At the Gold Valley nearly forty men are employed. Fifteen stamps are constantly running at the mill. The Alaska mine at Pike City has about fifty men at work, and is getting out rich ore.

THE GOLD VALLEY.—The Gold Valley mine is now in full running order, with nearly forty men employed. They have begun crushing ore in the mill, and fifteen stamps are continually kept running. A. Maltman has charge of the cblorination works.

Shasta.

IRON MOUNTAIN MINE.—At the present time there is little doing. The mill is idle, waiting for wood, a contract having been let. The mountains have been laid hare of timber for several miles around the mill.

A new tunnel has been started lower down and pushed in some 135 feet. A crew of men are also at work extending the boarding-house. The survey for a railroad track to connect with some point on the river is progressing.

WINDY CAMP.—S. Weil has been working on the sale of the Windy Camp property. The transfer has been made, but there are a few matters to settle as regards title. The purchasing parties will expend some $100,000 on the property as soon as a clear abstract can be shown.

THE EUREKA TELLURIUM.—*Free Press:* The Eureka Tellurium or Scherer mine and works will start up April 1st under the superintendence of Mr. Murdock. W. D. Swezey, the president of the company, will also give the mine considerable attention.

FRENCH GULCH.—The Gladstone mine is running twenty stamps and employing forty-five men. The ore averages well and the mine is in a prosperous condition.

The old Washington has a very rich ore body and is making hullion faster than at any time in the last twenty years.

Parties working in the Niagara report a phenomenally rich ore body.

The Myers miue is also running on some high-grade ore.

Wm. Stevens, who has been erecting the mill for Ellery Bros., reports the mill ready for operation. It will probahly he started this week.

Parties down from Trinity Center report the snow fast disappearing, and in a short time the country will he full of prospectors. Jack Strode continues to pile up rich rock, and the indications are that this district will produce between $200,000 and $300,000 this season.

The Minnesota mine on Spring creek has made arrangements to run through 200 tons of ore from Foster's mine.

Jack Karmeen reports matters at the Hidden Treasure very satisfactory. The mill erushes thirty tons daily.

Col. Jack Stowell is negotiating the sale of his claims to an Eastern syndicate.

The Uncle Sam has been using water power to run its mill since September, and from present appearances will not need steam before July. Supt. James shows some fine ore chutes as the result of last year's work.

OLD DIGGINGS.—Hart's Texas & Georgia is running twenty stamps as usual. A long tunnel to tap the lower levels is in progress.

Quartz Hill is to be under the management of Assayer Luckhart of San Francisco. The mill will he started soon.

OTHER DISTRICTS.—W. P. Miller's mill at Middle creek laid still two days this week on account of a broken rock-breaker.

John Doeblin, near Muletown, made a nice cleanup from his gravel claim. It paid from $8 to $10 per day to the man. With plenty of water this claim would be very productive.

Chapman & Voluntine have their hydraulic working and are doing effective work on Clear creek. Their ground ought to yield from $12,000 to $15,000 a month.

Charles Jones has his new mill running at Muletown.

Judge Reed of Igo is examining a new quartz find on Oak Run, thirty-five miles east of here, and will move his Huntington mill from Igo over there. The ore is free milling and averages $20 gold per ton. The ledge is eight feet wide and no waste in it.

Work is to be resumed on Oregon gulch drift diggings next week.

Trinity.

FISHER GULCH.—*Journal:* Messrs. Ralston & Spencer, who have a lease on the Fisher Gulch and Bonanza quartz mines in the Canyon Creek mining district, are prosecuting work on these properties.

DEADWOOD.—Charles Gilzcan has struck a very rich ledge. It is about 800 feet south of the Brown Bear mine. The ledge is small, but very rich, the gold being coarso and heavy.

J. N. McDonald, Tom O'Keefe and J. H. Blagrave commenced work this week on their lease in the Last Chance stopes.

Wm. A. Blagrave has discovered the western extension of the Brown Bear ledge. He has a lease on it, and is running a tunnel to tap it under the big slide north of the Brown Bear mill.

The Brown Bear Dump Co. started up their mill the latter part of last week and are running full time. The result of their last run was not satisfactory. They drove their tunnel farther under the dump, and from all indications their present run will prove satisfactory.

NEVADA.

STRIKE AT KENNEDY.—W. A. Nixon has made a strike in French Boy canyon. Assays of the ore run from $2000 to $4000 per ton and the ore chamber seems large. Considerable of the ore has already been taken out.

LYON COUNTY.—The *Times* says that C. T. Martin and W. H. Spragg, of Mason valley have discovered some pretty fair gold prospects in Mason valley, about six miles to the southwest of Yerington. The deposits are in the range of hills lying between Mason and Smith valleys, and are about two miles from the Walker river. Other prospectors have discovered gold in that section. It is low grade material, but the indications are that there is considerable of it as the ledges are large.

ON THE COMSTOCK.—Con. Cal. and Va.—1650 level—On the sixth floor in the new ore body, the second floor helow the sill floor of this level, the east crosscut started at a point 125 feet south of the vertical winze which connects with the 1600 level has been extended 26 feet, to a total length of 65 feet, passing through a quartz formation assaying $10 per ton, and reaching the old stope timbers. At a point in the south drift on this floor 85 feet south from the vertical winze a west crosscut was started and has been run 20 feet through low-grade quartz to the west or footwall. On the ninth floor the drift running south from the south end of the stope has been advanced 34 feet to a total length of 99 feet, its face being in porphyry. On the twelfth floor the east crosscut has been extended 5 feet to a total length of 70 feet, with its face in porphyry and low-grade quartz. From this east crosscut, to a point 18 feet in from its mouth, two drifts have been run, one to the north in low-grade quartz 12 feet, and the other to the south 9 feet in a formation carrying narrow streaks of ore which give an average assay value of $22.70 per ton. An opening has been made from the thirteenth floor up to the fourteenth floor 10 feet long and 6 feet wide, through low-grade quartz, porphyry and some clay. The stope started from the south drift, from the east crosscut, from the main north lateral drift, on the sill floor of this level at a point 20 feet from its mouth has been carried up 7 feet to a total height of 22 feet. This opening is 10 feet long and 6 feet wide, through ore 6 feet in width, lying against the west wall, and carrying on the average an assay value of $60 per ton. 1750 level—From the end of the drift running south from the south end of the stope on the fourth floor two crosscuts have been run, one to the east 15 feet through porphyry and quartz of low assay value, and the other to the west 9 feet through low-grade quartz to the west wall. A small portion of the ore extracted during the week came from the thirteenth floor above mentioned and the remainder from the opening made from the south drift from the east crosscut on the sill floor of the 1650 level, amounting to 52 tons, which assayed per car sample $46.92 per ton.

In the Ophir mine during the week the usual prospecting work was done in the 1465-foot level openings and in the old Central tunnel region. Most of the openings are in porphyry and low-grade quartz.

In the Hale & Norcross mine a west crosscut was started near the north boundary line on the 975-foot level and advanced 12 feet. The face is in porphyry and quartz. The south drift from the west crosscut No. 1 on this level was extended 8 feet to a length of 76 feet, and the face shows a narrow streak of fair-grade ore. On the intermediate level they have stopped work in the north drift and advaneed the south drift to a length of 31 feet. In it are porphyry and stringers of quartz. They extracted during the week eight carloads of ore averaging $29.68 per ton.

GOLD-BEARING QUARTZ.—William Ross, who has been prospectiug in the Fox range of mountains, about twenty miles north of Pyramid lake, says he has discovered a lead that is over one hundred feet wide, and that can be traced by croppings for over four miles. The formation in which the lead is situated is porphyry on the hanging wall and slate on the foot wall. The trend of the lead is almost due north and south, with a dip to the west. The ore has a bluish tinge, contains a high percentage of granite and contains consider-

able gold. The ore is free from base metal and sulphurets, the gangue being quartz and graphite. Assayers say it can be worked by ordinary mill process, as the gold is free. Samples of the ore have been taken to the State University. There is an abundance of wood and about fifty inches of water, with plenty of fall. The mine is about eighty miles due north of Reno, and is about forty miles from the terminus of the N. C. O. at Amedee. The owners are William Ross, Frank Dickinson, Seeley Trumbull, William Frost, James Sutcliffe, J. A. Bonham, J. F. Bonham, John Raser, Homer Bonham and B. F. Dickinson, who have located about 5000 feet of the lead.

ARIZONA.

SANTA MARIA COPPER MINES.—*Courier:* J. A. and F. A. Healy have sold their group of copper mines on the Santa Maria to San Francisco parties for $30,000, cash down. The group is located about eighteen miles below the Goodenough camp. The purchasers will work the mine on an extensive scale.

G. A. R. MINE.—Mohave *Miner:* Report comes from White Hills that an immense body of silver ore has been encountered below water level in the G. A. R. mine, owned by the White Hills company. Samples from the vein run over 1100 ounces in silver and four ounces gold per ton. This is the first strike of ore that has been made below water level and proves that the mines go down.

GOLD EXCITEMENT STAMPEDE.—There is reported from Jerome, an account of a strike of gold rock in one of G. W. Hull's mines, two miles south east of Jerome. The pay streak is fifteen inches in width and, it is asserted, runs $2,000 gold per ton. Over 100 people are camped on the ground and more coming in the same vicinity.

THE HOWELL.—The Howell mill is now being run day and night on ore from the Shelton mining group, on upper Lynx Creek, the Shelton people having made arrangements with Mr. Morse to mill their ore pending the arrival and erection of their fifteen stamp mill.

THE RIPSEY SHUT DOWN.—*Silver Belt:* The Ripsey mine, near Riverside, of which great expectations were entertained, has shut down after a few days' run of the mill, sufficient to demonstrate the fact that the ore could not be made pay. A few men are retained to run a drift in short distance, on the 300-foot level, to the ledge. If pay ore is not encountered there all work will stop.

For the past eight or nine months the company has been working a considerable force opening up the mine. A mill was erected on the Gila, four miles below Riverside; also a store and boarding-house and cabins for the employes. The expenditures amounted to about $70,000. All the appointments are complete and first-class; all that is lacking is pay ore.

It is another instance of building an expensive plant before a mine has been found to supply the ore. It is not a new experience. Unfortunately, it has been far too common in the West, and Globe district has experienced the same disappointment more than once, and is still feeling the evil effects of those disasters.

Every such blunder works harm to the mining industry.

OREGON.

WILL PUMP DIRECT.—The Tolo Mining Co. have switched on their idea of getting water on their placer mines with a flume, after spending considerable time and money in the endeavor, and will pump with steam from Rogue river direct. The flume built will be used for running tailings into the stream.

Josephine Co.

BOUGHT A MINE.—Ex-Collector of Customs Quinn, of this city, has bought the Hammersley mine in Jump-off-Joe precinct for $25,000.

Jackson Co.

THE ASHLAND MINE.—Capt. Jas. Carroll is having the Ashland mine experted. His option on the property expires next week.

BRITISH COLUMBIA.

LARDEAU CREEK.—The placer diggers on Lardeau creek are doing well, says the Revelstroke *Mail*. Charles Matheson picked up a splendid specimen a few days ago valued at $15. John Knowles has some splendid samples of gold, about $300, in nuggets, ranging in value from 25 cents to $10, and which he has taken out of the creek in the last few months.

IDAHO.

THE TIGER PUMP.—The Tiger Company is now putting in the heaviest pump that has so far been introduced into the Cœur d'Alenes. This will be on the ninth level, and will pump 600 gallons of water per minute to a height of 750 feet. The discharge pipe is nine inches in diameter. Altogether there are 75,000 pounds of machinery included in the pump and its connections. It is of the Reidler plan, and was furnished by Fraser & Chalmers of Chicago. At present the Tiger mill is working only one shift—the mine two shifts. It is doing very good work, and turning out concentrates of a very good grade. About sixty-five men are employed.

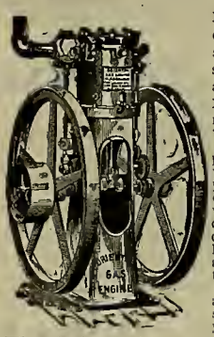
THE CŒUR D'ALENE.—Five loads of concentrates are sent in over the Cœur d'Alene branch each day from the Poorman and Gem mines and the other mines, except the Bunker Hill and Sullivan, are contributing their share of the business. There is some activity in nearly all of the mines now and the branch lines of the Northern Pacific are in better condition than they have been at any spring since the Cœur d'Alene was completed. The average depth of snow on the range last winter was only three feet, where it was from ten to sixteen a year ago. This snow has melted gradually this spring and there has been no material damage to the road.

SOUTH DAKOTA.

THE HOLY TERROR.—*Pioneer:* The Holy Terror mine is cleaning up fully $2,000 per day from their small stamp mill. The ore at the end of the drift is as rich as it was in the tunnel, and is now in about thirty feet. The rich streak continues all the way in and shows no signs of petering out, but is gaining in width. The owners have a fortune and are quietly working away and milling the rock. They ship to the mint at Philadelphia. The batteries of the mill have to be cleaned every night. The owners claim now to have enough ore to run the stamp mill for four months. A collection of forty-eight specimens sorted from the ore sent up were divided into four piles, one for each of the owners, who cast lots for first choice. The one who gained the first pick was at a loss to choose, as they were all very rich.

The clean-up for the forty-eight hours ending Tuesday night gave an even $8,000, or $1,000 a day.

The Oriental Gas Engine



IS THE BEST because it combines simplicity of construction with power and economy of space. It can be run with natural or manufactured gas or gasoline. It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

WATER WHEEL

CASCADE WATER WHEEL

Adapted to all heads, from **30 FEET TO 2000 FEET.** Our experience of **33 YEARS** in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.

JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals Without Quicksilver. By GUIDO KUSTEL, M. E.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 155 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, $3, postpaid. For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

The Explorers' and Assayers' Companion.

By J. S. PHILLIPS, M. E.

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

MINE BELL SIGNALS.

Adopted, Used and In Force in Accordance with State Law.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 19 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

Electrical Progress.

Electric Lighting in Mexico.

There are not yet many electric lighting plants in Mexico, and those now running have usually some feature out of common. That, for example, at Aguas Calientes is interesting. While successful in every way, it could not depend on its regular street and commercial lighting for an income. The earnings of the company for any particular month can be estimated with a fair degree of accuracy from the number of saints' days on the calendar. The station is so equipped as to supply churches with extra light at short notice, and often from 200 to 300 lamps are put into one church temporarily at a lucrative price. The six largest churches of the city are lighted by the company. Last Christmas time large crowds poured into the Cathedral to witness the special illumination. In the center of the altar was a life-sized figure of Christ. Radiating outward from this central figure were strips of silver gilt, and at the point of each of the radiations was a sixteen-candle power lamp. An additional 200 lamps were employed in a large inscription of the word "Maria." The effect was striking and the people were delighted. But the time when the resources of the station are most severely taxed is the feast of San Marcos. The Mexicans are born gamblers, and San Marcos is the great gambling feast of the year. Between the 20th of April and the 10th of May visitors flock into the city from all parts of the country to the number of 60,000 or 70,000, and among these there is a liberal admixture of American and European travelers. The city is given up to high revelry, and all gamble from high to low, according to their financial capacity. The headquarters of the play is the Hotel de San Marcos, where special apartments are gorgeously fitted up with mirrors and upholstery, and brightly illuminated with novel lighting designs. Around the tables are to be seen the youth, beauty and wealth of Mexico, and the game goes on night and day. Moreover, the celebrated San Marcos gardens are specially wired for colored lamps, and the whole scene is fairyland. Even if somebody "breaks the bank," the electric light plant comes out ahead. Two other curious features distinguish the plant. It uses wood for fuel in preference to coal at $15 a ton, and the station hands are paid daily for fear the affluence and opportunities of a whole week's wage all at once should be too much for them.

Electric Life Buoys.

A large electric company of Berlin, Germany, is making a life buoy for use on shipboard, which is fitted with an electric lamp so as to be visible at night in the water. The floating apparatus is made of waterproof linen, and is sufficient to bear the weight of three persons in the water, life belts being attached to the buoy. Inside the canvas buoy is a double wooden box containing an accumulator with gelatinous electrolyte, and it is capable of feeding an incandescent lamp for six hours. The incandescent lamp surmounts the floating buoy in a strong wire frame, and is further protected by an outer strong glass globe. When the apparatus is hanging on board ship, the weight of the lower portion automatically switches off the current, but as soon as the buoy is released and dropped into the water four powerful springs switch the current on. The accumulator will last for two months before requiring to be recharged, so that the apparatus can be employed on board ship where there is no dynamo. The apparatus weighs 100 pounds, but the accumulator can be made lighter, with, of course, a corresponding decrease in the duration of the light. A further and promising form of electric life buoy has now been proposed in the nature of a dirigible craft, such as have already been used successfully in warfare. It carries a motor and a reel of wire, and can be directed towards wrecks or any one struggling in the water. By reversing the motor can be made to rewind its wire or to come home with its burden. By day it carries flags, and by night its location is marked by an incandescent lamp on it. Any ship or life station that has an electric light plant can operate from deck or shore this life saver, and it is believed it will soon find its place among the best appliances of the kind.

Electric Light Photography.

Mr. Adamson, of Glasgow, Scotland, has been exhibiting a photographic apparatus using fifty-candle power incandescent lamps, about forty in number, arranged in a circle inside an umbrella-shaped reflector. The lamps are run up to double or treble their normal power at the moment of exposure. This, as every electrician knows, will not only blacken the lamps at once, but shorten their life at the same time. The arc lamp is now so perfect, its light is so much better than daylight for portraiture work, and the cost of maintenance and for current so small compared with that of the incandescent system, that the experts fail to see the reason for the adoption of incandescent lamps for such a purpose. Perhaps the greatest use of the arc light in photographic work now occurs in American newspaper offices, where resort is made to free illustration. The speed and neatness with which the latest sketches from the seat of war, crime or disaster are thus converted into blocks and are run through the press alongside type is considered marvelous by foreign journalists.

One of the highest medical authorities in England made a merited attack upon the medical electrician in a lecture delivered by him on February 11th before the London Institution. Taking as his subject, "Truth and Falsehood as to the Effect of Electric Currents on the Body," he showed the present state of our knowledge regarding the subject. Referring to the effects of the various currents on nerves, he showed a number of experiments and quoted Galvini's celebrated frog experiment. Some of the "quacks" advertise their electric belts and such wares in the stereotyped phrase, "Electricity is the Life," and Prof. Horsley showed the falsehood and deceit therein contained. The only legitimate purpose for which an electrical current could be used in medicine or surgery was to stimulate or call out action in some particular muscle, or to stimulate some other physiological action, such as secretion. But the currents required to do this must be powerful and intense. After speaking in very strong terms of C. B. Harness's Company and its quackery, he referred to electrical quackery having had to be slaughtered by public-spirited private individuals instead of by the real public prosecutor, whose real duty it was.

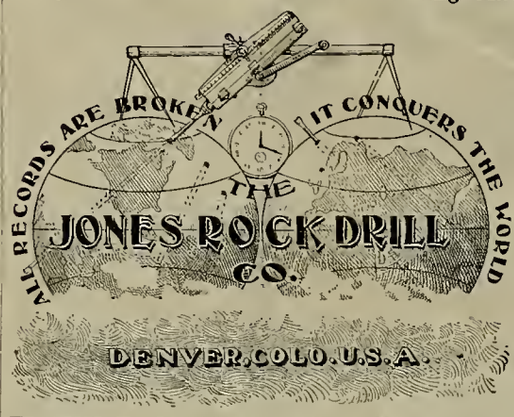
THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXV.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

From a letter dated Castel-a-Mare, ancient Stabiæ, September 2, 1794, by the same author, the following is quoted:

"Within a mile of this place, the mosetei are still very active, and particularly under the spot where the ancient town of Stabiæ was situated. On the 24th of August a young lad, by accident falling into a well that was dry, but full of mephitic vapor, was immediately suffocated. There were no signs of any hurt from the fall, as the well was shallow. This circumstance called to my mind the death of the elder Pliny, who most probably lost his life by the same sort of mephitic vapor on this very spot, and which is very active after great eruptions of Vesuvius."

There is a similar locality at Amsanctus in the ancient province of Samnium, at the temple of Mephitis. Virgil has made this locality famous in the following verse:

"There is a place, amidst Italia's land,
Of note illustrious, beneath mountains high,
Sounded aloud by fame through many a clime,—
The valleys of Amsanctus:—these with boughs
Dark buried on each side, a wood hangs o'er,
And in the midst a roaring cataract,
'Mongst rocks, with giddy whirlpools hoarse resounds.
Here a terrific chasm is shown, deep vent
Of ruthless Pluto; where a vortex vast,
From bursten Acheron pesrif'rous yawns:
Therein Alecto, now-abhorred name!—
Plunging rom sight, disencumber'd earth and Heav'n."
(Eneid, book VII, 708.)

In "The Natural History of Vesuvius, 1743," before quoted, fol. 195, may be found a very detailed account of the "mossetto". First Grotto del Cane is described: "Such is what we call the mossetto, of which we have others in the neighborhood of Naples and in different parts of the kingdom. * * * * The Lake of Averno might anciently pass for a kind of mossetto, for the Greeks gave it the name of 'aorne' because its exhalations were so pestilential as to kill the birds that accidentally flew across it (aorne signifies a place without birds, or which the birds shun or dare not pass without danger). * * * * We call, then, a mosetto, a steam which is deadly to all animals that remain in it, that extinguishes a flame suddenly, not by its stench, nor coldness nor heat, nor any visible or apparent quality, but from some occult cause which our senses cannot discover" (fol. 196). "We say that this vapor extinguishes the flame, for you no sooner let down a lighted torch or candle into its atmosphere than it goes out as suddenly as if plunged into water (fol. 197). * * * We shall say nothing of a third kind of exhalation which we may call 'artificial mosetti,' such as the steam of new wine when in the fat, that of several chemical mixtures, the steam or smell of charcoal or sulphurous coal and, lastly, the nuisance of air when long pent up in the same compass (fol. 198). Our peasants know the mosetto or pestilential exhalation by several marks—sometimes the grass is violently agitated, chiefly in those places that serve as vents to the exhalation; sometimes the plants appear all dead and withered by the malignity of its venom; and sometimes they know by the birds, lizards and insects which lie smothered in its course (fol. 200) * * The method we took to discover their course and extent was by light and torches we carried with us. These, when held in the atmosphere of a mosetto, immediately went out and the smoke pointed the direction of the exhalation. * * * * We made some experiments on water tainted by our exhalations into which we put several sorts of fish. Undoubtedly they felt some pain, for they darted about with surprising velocity and signs of uneasiness, often thrusting their heads above the surface, which they seldom do when the element is pure. Eels and frogs seemed to bear it better, though they seemed like the others to be quite spent and lay on the surface with their bellies turned up as if dead. Whether the water purged itself from the contagion soon or from some other cause, they all revived (two or three eels excepted), and being removed to clean water, soon grew as well as ever (fol. 213)."

Daubeny refers to the mosetti in southern Italy: "About a mile to the east of Mount Vultur, in a place called 'Rendina,' is a mosette or exhalation of some noxious vapor which produces a sharp, smarting sensation on the organs of sight, smell and taste and causes a fainting in those who breathe it freely. * * * * There is one spot, however, in the midst of a torrent which flows along the valley, called 'Vado Mortale,' from the nature of the mosette existing there. This, which is carbonic acid, attains usually to the height of four or five feet, so that it is constantly fatal to animals that pass the stream at that point." (Description of Active and Extinct Volcanoes, (fol. 141–143.)

The phenomenon of dying fish is repeated in California, many being from the same cause killed in Clear and Buena Vista lakes.

(To be continued.)

WANTED!

Mining superintendent to take charge of a silver mine in Mexico. Must be of good habits and thoroughly reliable in every respect, and have a practical knowledge of mining and milling silver ores and able to speak Spanish. No other need apply. Address BOX J,

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, March 21, 1895.

The rise in silver is variously accounted for —the adjournment of Congress, the monetary conference, the attitude of Germany, the Japan indemnity are among the causes assigned. It is probable the real reason is the recognition by England of the future futility of attempting the continued demonetization of silver, the hoarding in anticipation of the terms of the payment of China's war debt to Japan, which is practically the usual matter of supply and demand. Like everything else, the question will work itself out.

New York Metal Market.

NEW YORK, March 21.—PIG IRON—Scotch, 19@20c; American, 9.50@12.50c.

Mining Share Market.

SAN FRANCISCO, March 21, 1895.

The market opened weak, with some improvement during the week, there being nothing of note in the daily transactions. The rise in silver will first favorably affect the Comstock and other "going" silver properties, as there cannot be expected any general resumption of work in suspended silver mines till there is assurance that the present advance is something more tban a spurt.

There is a new find of ore in Occidental Con., and the north drift from the west crosscut, 500 level, continues in $40 ore.

The directors of the Holmes Mining Company have ratified the contracts with the syndicate of Chicago and foreign capitalists, referred to in last week's issue, for working the tailings and low-grade ores of the company and also cleaning up its mills. Work will shortly begin at Belleville.

The Gold Run Placer M. Co. has bought the mines of that name south of Golcouda, Nev.

Salt Lake parties are again reported to have bonded some Meadow Lake mining claims for $50,000.

Bewing, Moreing & Hooper, of London, are reported uegotiating for the Rawhide mine on a million-dollar basis.

At the auuual meeting of the Chollar Mining Company 98,822 shares were represented and the following officers elected: A. K. P. Harmon, president; Thomas Cole, vice-president; and Thomas Anderson, D. C. Bates and E. P. Barrett, directors. Charles E. Elliott was re-elected secretary. His statement showed a credit balance of $7157.82. H. M. Gorham was re-elected superintendent. His report showed that the company made $800 over all expenses during the past month.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 12, 1895.

535,662.—FRUIT EVAPORATOR—A. H. Blackburn, Petaluma, Cal.

535,663.—CHIMNEYS—A. H. Blackburn, Petaluma, Cal.

535,673.—LOCOMOTIVE—M. B. Bulla, Yuma, A. T.

535,674.—BICYCLE—C. A. Coey, Fairfield, Wash.

535,683.—ORE CRUSHER—W. G. Dodd, S. F.

535,684.—CAR COUPLING—W. Dunlap, San Diego, Cal.

535,694.—CAN HEADER, ETC.—J. W. Gbeen. Portland, Or.

535,445.—PHONOGRAPH—L. W. Glass, S. F.

535,588.—FOUNTAIN PEN—P. D. Horton, Oakland, Cal.

635,541.—BATTERIES—A. Hougb, S. F.

535,805.—RAILWAY TOOL—B. Molloy, Golconda, Nev.

535,718.—RESPIRATOR—R. Nagler, S. F.

535,770.—WOODEN STOPPLES—R. F. Ridebaugb, Tacoma, Wasb.

535,771.—CUTTING MACHINE—F. J. Richards, Needles, Cal.

535,742.—LADDER—Tbos. Sooy, Gridley, Cal.

535,424.—DRAG SAW—A. T. Stimson, Bayside, Cal.

535,634.—CHIMNEY CAP—F. C. & H. A. Stober, Sacramento, Cal.

535,635.—CARD RECEIVER—J. T. Stone, Oakland, Cal.

535,472.—PUNCH AND DIE—N. Troyer, Astoria, Or.

535,474.—EGG BEATER—C. H. Warrington, Stockton, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

THE CALIFORNIA DEBRIS COMMISSION having received an application to mine by the hydraulic process from George Wheeler, in the Grizzly Flat Mining Claim, El Dorado county, Cal., to impound tailings behind brush dams below the mine, gives notice that a meeting will be held at room 92, Flood building, San Francisco, Cal., April 1, 1895, at 1:30 P. M.

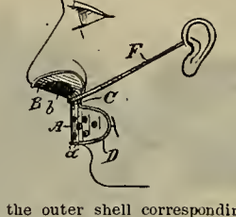
Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are wortby of special mention:

RESPIRATOR.—Robert Nagler, San Francisco, Cal. No. 535,718. Dated March 12, 1895.

The object of this invention is to provide a light, rigid device, properly shaped to fit over the mouth and nostrils of the wearer, with a means for detachably applying a suitable porous material through which respiration will take place, and fitted between an outer shell and an inner covering; perforations made



tbrough the outer shell corresponding with tbe apertures of tbe nostrils and the mouth; and an inner flexible lining, impervious to air, adapted to rest upon the edges of the nostrils and over the mouth, and perforated to correspond with the outer plate; together with an elastic or other attachment for holding the whole in place, so that air which enters the lungs may be purified from injurious particles which may be floating in the atmosphere, or so that it may be medicated for a treatment for lung and throat troubles.

CHIMNEY AND VENTILATOR CAP.—F. C. and H. A. Stober, Sacramento, Cal. No. 535,634. Dated March 12, 1895. The object of this invention is to provide an improved chimney and ventilator cap. It consists of a chimney or body portion converging from the upper end downwardly, pipes or tubes entering the same between the ends converging from their bases upwardly and outwardly, a cap of large diameter above the top of the cbimney or body portion, and arms depending from the cap, extending down along the exterior of the chimney or body with their lower ends formed into hooks adapted to receive rods or guides for anchoring the device in position.

MESSAGE AND CARD RECEIVER.—John T. Stone, Oakland, Cal. No. 535,635. Dated March 12, 1895. This invention is designed to provide a convenient device which will enable a visitor to leave a card or message for tbe person visited, and to transfer said card after writing upon it to a closed receptacle, leaving a blank card in its place for the next visitor. It consists of a case having an opening through which the cards are exposed, a movable spring-actuated follower, a slot or opening through which cards may be introduced when the follower is depressed, a second closed chamber in line adjoining the first, having a slot between the two corresponding with tbe position of the exposed card, and a mechanism wbereby the card may be advanced from the containing case through the slot into the second receptacle.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators.

BY P. M. RANDALL.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulæ and Rules; Flow of Water Through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tnbes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels, Extensive Tables; Rougb and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price $2.00, postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Assessment Notices.

BRUNSWICK CONSOLIDATED GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley Mining District, Nevada County, California.

Notice is bereby given, that at a meeting of the Board of Directors held on the 20th day of March, 1895, an assessment (No. 8) of Two cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room 56, Nevada Block, San Francisco, California, or to the Treasurer, J. J. Halpin, 57 Broadway, room 57, New York City, State of New York, on or before the 20th day of April, 1895.

Any stock upon which this assessment shall remain unpaid in San Francisco, on the 20th day of April, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. STADTFELD JR., Secretary.

Office—Room 56, Nevada Block, San Francisco, California.

FAIRFAX VILLA COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Fairfax, Marin county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of February, 1895, an assessment, No. 2, of one hundred dollars ($100) per sbare was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 56, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of March, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 16th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. STADTFELD, JR., Secretary.

Office—Room No. 56, No 309 Montgomery street, San Francisco, California.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 20th day of March, 1895, an assessment (No. 18) of Ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 69, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

CHALLENGE CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Gold Hill, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth (19th) day of February, 1895, an assessment (No. 18) of Five Cents (5c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the twenty-sixth (26th) day of March, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the sixteenth (16th) day of April, 1895, to pay the delinquent assessment, together with cost of advertising and expenses of sale.

By order of the Board of Directors.

C. L. McCOY, Secretary.

Office—Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Auburn, Placer county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the eighteenth day of February, 1895, an assessment (No. 5) of Two (2c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, Room No. 28, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on WEDNESDAY, the seventeenth day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. R. SPINNEY, Secretary.

Office—No. 310 Pine street, Room No. 28, San Francisco, California.

IOWA MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia City, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 6th day of March, 1895, an assessment, (No. 20) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 2, 419 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 9th day of April, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 27th day of April, 1895, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. L. THOMAS, Secretary.

Office—Room 2, 419 California Street, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Geo. W. Edwards, in the Blacklock Mine, near Placerville, El Dorado Co., Cal., to impound tailings behind a brush dam in Spanish Ravine, from Kelly & Matheny, from Rattlesnake Bar, near Auburn, Placer Co., Cal., to deposit tailings on bank of American River; from O. M. Henry, in the Dry Gulch Mine, near Volcano, Amador Co., Cal., to deposit tailings behind a dam below the mine; from J. K. Williams, in the Saw Mill Flat Mine, near Whiskytown, Shasta Co., Cal., to deposit tailings in an old hydraulic pit; and from Thomas Ewing, in the Mooney Placer mine, near Placerville, El Dorado Co., Cal., to deposit tailings in old hydraulic pit, gives notice tbat a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on April 1st, 1895, at 1:30 P. M.

Coast Industrial Notes.

—British Columbia sawmill men are supplanting white labor with Japanese.

—Los Angeles reports that the new smelter will be in operation there by July 1st.

—Fourteen vessels have been chartered for the Alaska salmon business, to be ready after April 1st.

—N. E. Ayers & Co., of Portland, Or., have incorporated under the name of The Portland Rolling Mill.

—An order for 170,000 bricks has been placed for the construction of a smelting works at National City.

—Only 25% of the shingle mills on the Portland line of the Gray's Harbor country were running March 1st.

—The Oakland Gas Light and Heat Company are about to put in new machinery aggregating in cost $100,000.

The passenger receipts of the Seattle Consolidated Street Railway Company for 1894 show a decline of $21,823 as compared with 1893.

The Canadian Pacific railway earnings for the week ending March 7th were $264,000; for the same period last year, $308,000. This is a decrease of $44,000.

F. T. Sutherland, the manager of the Pacific coast agency for the Jones Rock Drill, is now located with the Parke & Lacy Co., 21 and 23 Fremont St., this city.

The Sailors' Union has declared a strike from San Diego to Puget Sound. For two years the rate of wages on the coast has been $25 a month, and now they demand $35.

Steamers to Humboldt bay ports have cut freights on lumber and shingles in retaliation upon the lumber schooners, which have been carrying passengers below the regular rates.

The Atlantic and Pacific is getting the cream of hauling the California fruit crop. Five and six through trains of oranges and dried fruit pass through Winslow, Arizona, daily.

The Merced Gold Mining Syndicate of California have ordered of the Gates Iron Works a 16x42 direct-acting hoisting engine with Corliss valves, steam brakes and the latest improvements.

—Commencing next Saturday the steamer Dora will connect with the Pacific coast steamers at Juneau, carrying the United States mail between that port and Sitka, Karluk, Sand Point and Onalaska.

—The Los Angeles Railway Company incorporated in this city last Tuesday, to construct and operate street railroads in Los Angeles. Directors—Lovel White, Thomas Brown, John D Bricknell, A. H. Payson, George Stone, Alfred Borel and M. H. Sherman. Capital stock, $4,000,000; $3500 has been subscribed.

—The Piedmont Consolidated Cable Company was sold under the hammer at Oakland last Tuesday to Charles R. Bishop, vice-president of the Bank of California, for $82,000, he being the only bidder. The bondholders of the company are frozen out and the stockholders may be held responsible for the million-dollar indebtedness.

—Liens aggregating over $100,000 have been filed in San Bernardino against the Nevada Southern railroad by mechanics and men, including one claim by the original contractor on the construction of the road. From the character of these claims they will take precedence of other indebtedness against the road and will be foreclosed at once and the road sold.

—The Moraga Valley Railroad Co. has incorporated to build a railroad in Contra Costa and Alameda counties, 35 miles from Walnut Creek to San Francisco bay. The directors are A. A. Grant, of Albuquerque, N. M.; J. T. Williams, of Oakland; J. R. Grant, of Los Angeles, and A. McDonnell and J. A. Burton, of this city. The capital stock is $500,000, of which A. Grant has subscribed for $22,500, J. R. Grant for $10,000, McDonnell and Burton for $1000 each, and Williams for $500.

DELINQUENT SALE NOTICE.

REED MILL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Ferguson Mining District, Helene, Lincoln county, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment No. 1, levied on the 31st day of December, 1894, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
J. H. Isham, Trustee	6	500	$10 00
J. H. Isham, Trustee	7	2,500	50 00

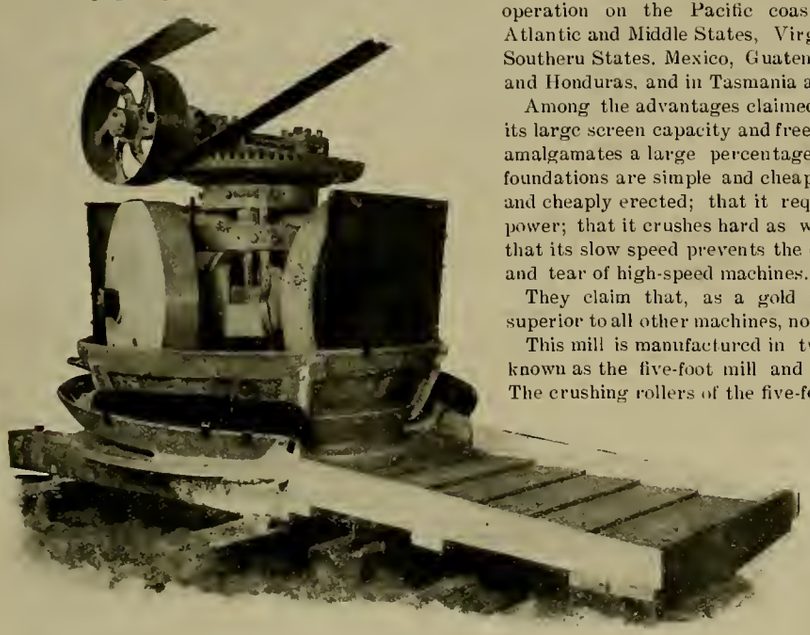
Improved Bryan Roller Quartz Mill.

On this page is presented an illustration of what



IMPROVED BRYAN ROLLER QUARTZ MILL.

is known as the Improved Bryan Roller Quartz Mill; directing the miners' attention to a machine that, in these days of new inventions, proves that the old principles of milling are hard to excel.

The old arrastra, which probably was used earlier than stamps, is still in use in its crude form, and, in some instances, is considered superior to new and improved machinery. The arrastra "did the work" and did it well, and so did the Chilean mill, which may be considered developed from the arrastra. But greater capacity was required, and as the stamp battery at that time was the only machine arranged for a continuous crushing process, it took the lead, as its capacity was so much greater.

As for amalgamation, the principle of the arrastra and Chilean mill is by some claimed to be superior. Many different kinds of roller mills were tried, but they were too complicated and difficult to keep in repair, and the oil could not be prevented from dropping into the pulp, which made the quicksilver unable to amalgamate with the gold. It was after many years of experimenting and with great expense that the manufacturers of this mill were able to place it on the market—a machine that embodied all the advantages of the crude arrastra and Chile mill, and, at the same time, possessed the simplicity and durability that were required in mining machinery.

At present about a hundred of these machines are in successful operation in this country, as well as in Mexico and other places. This mill has certainly passed the experimental stage, as the manufacturers inform us that they are in successful operation on the Pacific coast, as well as the Atlantic and Middle States, Virginia, Georgia and Southern States, Mexico, Guatemala, San Salvador and Honduras, and in Tasmania and in Australia.

Among the advantages claimed for this mill are its large screen capacity and free discharge; that it amalgamates a large percentage of gold; that its foundations are simple and cheap; that it is quickly and cheaply erected; that it requires a minimum of power; that it crushes hard as well as soft ore; and that its slow speed prevents the extraordinary wear and tear of high-speed machines.

They claim that, as a gold amalgamator, it is superior to all other machines, not excepting stamps.

This mill is manufactured in two sizes, of what is known as the five-foot mill and the four-foot mill. The crushing rollers of the five-foot mill are forty-four inches in diameter, with a seven-inch face, and weigh 3650 pounds each. The four-foot mill has smaller rollers, weighing 1200 pounds each, but is manufactured so that a weight drum can be used if necessary; and the claims of wear and tear, as set forth by the manufacturers, are that a set of wearing parts for a five-foot mill will crush from four to eight thousand tons of ore, and a set for a four-foot mill will crush from fifteen hundred to two thousand tons of ore.

The five-foot mill requires but six-horse power, and its capacity is from twenty-five to thirty-five tons per day of twenty-four hours.

The four-foot mill requires five-horse power, and crushes from twelve to twenty tons. The four-foot size is also made in sections suitable for mule-back transportation.

The Risdou Iron and Locomotive Works, of this city, who are manufacturers of this type of mill, will take pleasure in giving further particulars, as they manufacture this mill in combination with plain gold mills, steam or water power; concentrating gold mills, steam or water power; and wet-crushing silver mills, steam or water power.

This mill is also well adapted for re-crushing jig tailings from coarse concentration works before concentrating on vanners.

Rix Air Compressors.

The accompanying cut shows a vertical air compressor, built by the Fulton Engineering and Ship-Building Works for the Whitlock mine, after the designs and patents of Edward A. Rix, of this city. It is rather an unusual thing to see a vertical single-acting compressor in these days, where a cheap machine seems to be the primary consideration in the purchaser's mind. This compressor cost just twice as much as the ordinary machine of the same capacity, and inasmuch as Mr. William Johns, manager of the Whitlock mine, is well known as one of the most economical mine operators on the coast, there must be some good reason for his investment; and it consists in this: In 1880 Mr. Rix built for the Sierra Buttes and for the Plumas-Eureka mines, under the management of Mr. Johns, two vertical compressors of this same type, the one at the Sierra Buttes operated continuously for eight years until the mine was closed and was then sold for 50% more than its first cost, while the one at the Plumas-Eureka has been continuously at work since 1880 and fifteen years of service has not altered its efficiency. The ordinary replacing of worn valves and springs is all these machines have cost for repairs. After such faithful service, Mr. Johns concluded he would have no other for the Whitlock. Looking at the compressor from a mechanical standpoint, it is quite remarkable that even after fifteen years this construction should still be the most economical single stage compressor built. The reasons are simple: It is vertical, and the cranks being at 180° the weights of the moving parts are completely balanced. The outlet valve, which covers the entire end of the cylinder, permits the piston to touch it at the end of each stroke and thus insures a complete displacement of the air. The engine, which lies at 90° from the compressor cylinder, is also connected at the same angle with the compressor cranks, thus being under full steam while the com-

TABLE OF CONTENTS.

ILLUSTRATIONS.—Improved Bryan Roller Quartz Mill; Rix Air Compressor, Built by the Fulton Engineering and Ship-Building Works, 193; Electric Power Line Between Bodie and Green Creek; Penstock and Flume; Generator and Water Wheels in Operation, 195; Generator Switch-Board at Power-House; Power-House at Green Creek; Summer View on Pole Line, Looking East, Ten Miles From Bodie; Summer View on Pole-Line, Looking West, Ten Miles From Bodie, 197. Electric Pump on Fifth Level, Gover Mine, Amador Co., 198.

EDITORIALS.—Improved Bryan Roller Quartz Mill; Rix Air Compressors, 193. Miscellaneous, 194.

SCIENTIFIC PROGRESS.—A Tubular Frame House; Parts That Do Not Grow Old; Miscellaneous, 200.

MECHANICAL PROGRESS.—The Wage Worker in Germany; Wood-Pulp Pipes; To Clean Machinery; Tendency of Boiler Plates to Crack, 201.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 198-99.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 206.

MISCELLANEOUS.—Concentrates, Personal; Obituary, 195. Electric Power Transmission, 196-97. A California Stamp Mill; Electricity in the Gover Mine; Colorado Mining Companies, 198. Surpassing Edison and Tesla, 201. Uses of Sawdust; Natural Bridge in Oregon; Artificial Whaleboue; 1,000,000 Acres, 204. Witwatersrand Gold Product, 205. Recent Patents, 206. Coast Industrial Notes, 207.

FROSTS in Solano county have destroyed the cherry crop: in Florida the orange crop. Droughts in Nebraska have destroyed the corn crop: in Georgia the cotton crop. In New York the louse has eaten the hop crop and in North Carolina something has happened the rice crop. The rural animal crop has also met with disaster. The gold crop seems the only one unaffected, and amid such wide devastation it is some comfort to know of one crop that is neither diminished nor destroyed.

PROBABLY no other manufacturing industry in the country is to-day so prosperous as that of bicycle making. It has been calculated that $250,000 a month is now being sent from this State eastward for the "silent steeds." This is a strong argument for the establishment of a bicycle factory here. Probably, "all things being equal," a Californian could be induced to buy a California-made bicycle were it shown to his satisfaction that it was at least as good as the Eastern-made article, were it furnished him at a little less than it costs him now after freight and three distinct profits are added to manufacturers' cost prices.

THE copper refinery in Anaconda, Montana, by the electrolytic process, has ceased to be an experiment. It is daily turning out fifty tons refined copper. In the acre of buildings are 600 vats. In these the copper anodes are placed, the crude copper precipitated therefrom, the electrolytic current transferring it to a thin sheet of copper, of which each anode furnishes two in about twenty days' time. It is the present intention to build a refinery at Great Falls three times the size of the Anaconda plant, the water of Black Eagle Falls to be utilized in furnishing the requisite electricity.

A CITY JOURNAL has started anew the controversy regarding hydraulic mining and, in well-meant effort to aid the miner, has elicited considerable bitterness from the valley press and incidentally has given the anti-debris association a chance to say over again much that it has been mouthing and mumbling for twenty years. It is believed the better way—the progressive way—is to conciliate, to reason together, to help the State rather than start snarling and snapping that can do no good and may do great harm. The miners have right on their side; they are securing public opinion also, slowly but surely, and the justice of what they ask is being generally conceded, even by many of their former opponents. To arouse antagonism and incite bitter rejoinder is never wise, and now particularly ill-timed.

THE railroad's attempted selection of mineral lands has brought a snow storm of protests from the miners, who justly view the attempted grab as a direct menace to their interests. The whole thing is characteristic: the attempt to include mineral lands, the "advertising" of applications in the obscurest manner at a time when deep Sierra snow made it a life and death matter for many a miner to attempt reaching the Redding land office, the evident valueless character (from an agricultural point of view) of much of the land sought to be absorbed; all are illustrative of the spirit that must be met by organized action on the part of the Califoruia Miners' Association. All that could be done has been done, but the fight is by no means over, and work and money are still needed in the effort to keep public and private mineral lands in this State free from any real or apparent railroad title.

AT the recent session of the Manufacturers' Association, discussing urgent present needs, Geo. W. Dickie, of the Union Iron Works, said:

I made some figures the other day for a San Francisco house of the cost of a special steamer for service on this coast. The cost was, say $80,000. I was then asked to give the monthly cost of running this vessel in this State. In this case the State, city and county taxes just equaled the captain's pay, and it further showed that if our clients should have their New York agent get a ship built there, register her in the New York custom house, the annual expenses saved in taxes would enable the owner to give the preference to an Eastern builder of $20,000. This is the legislative encouragement we get for home industry.

Just so, and only by united and persistent effort can such untoward conditions be changed. The Association has made permanent organizatiou, and by continuous demonstration that this is a case where personal interest and public good go together, the home manufactures in every department of industry will be benefited.

THE Superior Court of Nevada county made a decision last Tuesday that will probably stand until the defendants can get the case before an appellate court. It is the case of Hawke vs. Webber and Quigley. The decision, in effect, is that in Nevada county no one can prospect for mineral on "railroad land," or land listed to the railroad, but which is unpatented. In the case of the land at issue in the suit, the General Land Office has not determined its character, nor has a patent been issued. The decision denies the defendants the right to prospect upon such land. It has been supposed that until patent was issued to the railroad company for the lands it claims, or for any lands, a miner could show that it was mineral land, and protest against issuance of such patent. If he be denied the right to prospect, how can its character as mineral land be shown? This may be law according to Judge Caldwell, but it will not be accepted as final by the miners of Nevada county or the State.

THE report of the Broken Hill Proprietary Company, issued last month, is received. It is interesting to American readers; it is the report and statements of accounts of the largest profitable silver mine in existence; it is about as far removed from this coast as it can well be; the system of bookkeeping is a most elaborate detail of infinitesimal details; the profits are princely; the methods almost totally different from ours. The present report of this immense silver mine in New South Wales is for the six months ending Nov. 30, 1894. During the previous year there was produced 6,750,569 ounces of silver 999 fine. There were 4079 ounces of gold produced in the same period. The cost per ton of the bullion was $6.95 in our money; five years ago the corresponding cost was $10.79. The general manager estimates 1,000,000 tons of payable oxidized ore in sight, besides as much more concentrating ores and sulphides. During the year the cost per ton of production was reduced from £2 12s 6d per ton to £2 3s 7d. The net profit for the six months ending Nov. 30, '94, was £343,216 17s 8d. On that day the assets of the company were £982,987 11s.

ENGLISH purchasers of or bidders for California gold mines usually evince a preference for what they term "a going concern"—that is, a bullion-producing mine, though apart from untoward experience there is no reason for the preference. The purchasers of a "prospect" have generally come out as well as buyers of developed, ore-producing mines. The California interpretation of the word "prospect" is wider than that given it by insular residents. With us, "prospect" and "prospector" have wide latitude of meauing. A "prospect" is generally more than a dictionary definition of the word implies. It is a mining property of at least sufficient value to justify the expenditure of considerable time and money in exploiting, exploring, securing title and developing, usually to the extent of the owner's financial resources. A "prospector" is by nature a little disposed to be too sanguine, such disposition being toned down by experience, but is withal a practical, experienced man who is unlikely to spend any time or coin on a valueless piece of ground. He may want too much for his claim, but under the circumstances cannot misrepresent it in such a way that his misrepresentations cannot be found out. If a "going concern" is profitable, the question arises why is the owner willing to sell, and a mistake in buying "a going concern" is always more costly than error in the purchase of "a prospect." It seems that the attention of purchasers can justly be given "prospects" as well as "going concerns," though owners of the former often stand in their own light by the excessive statements made or the excessive prices demanded.

CONSIDERABLE Eastern and foreign money is now being invested in California gold mining properties. It would be better were our own people, State or coast residents, to develop these paying properties and retain the dividends to further develop our resources, employ labor and build up the commonwealth; but it is better even to have outside enterprise come here and carry off gold than to let it eternally lie dormant. It will at least add to the aggregate wealth of the world when taken out of the hills and coined. A great objection to foreign control of our mines is that about the first thing an English company deems it necessary to do is to cut down miners' wages. We are told that "California must settle down to the Eastern level." It is also argued that "the East" is settling down to the European level, and Europe is probably settling down to the Asiatic level. The Asiatics are supposed to have no further depths of wage depreciation to reach. It is not here proposed to thrash over old straw in discussing rates of wages or the rights or wrongs of "labor" or "capital;" but it is a manifest fact that depreciation in the price of any article always induces proportional decrease in the quality of the product purchased, in any case where such depreciation is possible.

THE latest exposure of fraud in the mining world is in the case of President Haup, of the "Montana Mining, Loan and Investment Company." The usual swindling scheme is shown in the evidence at the trial. The company was organized three years ago, with an alleged paid-up capital of $12,000,000; a dozen worthless claims were secured, stock issued and sold to innocent investors, the whole thing being a repetition of a practice so common as to rank with the gold brick swindle and other bunco games. It is here referred to, to emphasize an assertion so often made in these columns—the downright dishonesty of prominent men allowing the use of their names in setting up such swindles. The present Governor of Montana and other prominent and wealthy mining men were at first in the corporation. True, they promptly withdrew when they found the whole thing was a fraud, but the mischief was done. While no charge of fraud can be laid against them, they tacitly endorsed the scheme, and lent such assurances as induced victims to pay money in who would not have lost their coin had it not been for belief in the financial integrity of these men, and, naturally, in the worth of what they fathered. It is, of course, unnecessary to expect that men eager to invest in wild-cat schemes are to be specially protected, as a matter of sentiment, but, as a matter of business, it is the duty of prominent mining men to expose fraudulent "mining" schemes, instead of endorsing and supporting them. The plea that they didn't know the scheme was a fraud is a poor one. The slightest exertion of ordinary business care would enlighten them as to its true character, and the fact that they themselves lost no money shows their own absence of confidence in the concern. Nothing more injures reputable and worthy mining investments than this too common practice of prominent mining men prostituting their reputations by allowing their names to be used as bait by those who fish for gudgeons; and those who charge that there are solid considerations for the permitted use of such names often have very natural reason for such assumptions. This particular concern was more of a lottery than anything else, and had no connection in any way with mining.

Concentrates.

THE Hite mine, Hite's cave, Mariposa county, is now reported bonded.

THE $64,000 shortage in the Carson, Nev., mint seems to be a plain case of stealing.

J. H. WILSON, of Red Bluff, has bonded his Oro Plato, Arizona, mine to Jno. W. Gerritt for $50,000.

THE owners of the Alpha mine are about to build a concentrator on Four Mile creek, Three Forks, B. C.

THE Supreme Court of Germany has cancelled the patent of the MacArthur-Forrest process in that country.

THE Willoughby mine at Funter bay, Alaska, has been sold to California men who will build a mill this summer.

THE Anti-Debris Association now holds secret sessions, the members being bound not to divulge their deliberations.

THE Zeile mill, Amador Co., which has been shut down for repairs at the mill and mine, is ready to resume crushing.

THE Burnt River G. M. Co. has organized in Portland, Or., to work gold bearing bars on Burnt river, Eastern Oregon.

THE Oregon Gold Mining Co. is about to resume work on the Red Jacket mine, Cornucopia district, Eastern Oregon.

THE Nation nickle mine in Churchill Co., Nev., is being fitted up with new machinery. A smelter is to be built in May.

THE Ashland, Or., mine will not be sold for the present, in the hopes that it can be disposed of at private sale for a fair figure.

MONTANA papers think the Anaconda people are about to absorb the Parrott properties—Parrott, Moscow and Little Minah.

RIVERSIDE sends word that "the miner's vote of the county will be heavier in four years than the vote of the orange-growers."

THE Rapid *Journal* says it costs $70 a day to run the Holy Terror gold mine in the Black Hills, and that the daily output is nearly $2000.

IT is the firm of Peck Brothers that bought the tailings of the Holmes and Caadelaria mining companies. The centrifugal process will be used.

A STAMP MILL has been ordered, and work on the Rose Hill gold mine at Grass Valley will go on under the superintendency of Supt. J. M. Wishart.

ALBERT HEDGER, of this city, is putting in and will operate some hydraulic mining machinery for the Red River Mining Company, at Elk City, Idaho.

THE first shipment of bullion from the Pilot Bay smelter was made last Saturday, consisting of two carloads which goes to the refinery at Aurora.

THE Copper Queen Company near Globe, Arizona, propose putting in an electrical plant, which will involve the transmission of power nearly fifty miles.

THE Argonaut Mining Company, Amador Co., have commenced suit against the Kennedy Mining Co. for $325,000 damages for alleged trespassing upon their ground.

THE Virtue, Baker Co., Or., mine's second clean-up for March amounts to 420 ounces, or $7980, making a total of nearly $13,000 for twenty days' run with twenty stamps.

A COMPLETE electric plant is to be put in at the Alaska mine, Pike City, Sierra county, of sufficient power to run all the hoisting and pumping machinery, and to light the mine and works.

THE owners of the Gladstone mine are coming to Shasta county to reside. They are among the wealthiest people in Cleveland, Ohio. The property is now on a self-sustaining basis.

THE *Argus* reports that subscriptions to the amount of $700 have been received at Auburn, Placer Co., to swell the fund of the Miners' Association and to be used in securing required legislation.

THE Shasta *Courier* says that the new owners of the Iron Mountain mine will not be likely to build a railroad to Red Bluff, because when they complete their reduction plant they will not ship ore.

F. AND S. MCCLOSKY, brothers, employed by the Union Mining Company of Cripple Creek, Colorado, have been arrested, charged with having stolen $100,000 worth of ore from the company.

MESSRS. SILVERMAN, Warren, Coram and Palmer, of Butte, Montana, have bought the Poorman, Novelty and California claims, Rossland, B. C., for $20,000. They intend to organize a company and stock the properties.

A TUOLUMNE PAPER hears that an English company has been given a bond on the Rawhide, Alameda and App mines and all the stock of the Tuolumne County Water Company. The price agreed upon is said to be $2,000,000.

THE following are recent Idaho incorporations: Idaho Consolidated Gold Placer Mining Co., of Pierce City, Idaho, $125,000; Alta Gold Mining Co., Boise, Idaho, $1,500,000; Canyon Creek Canal and Irrigation Co., Idaho, $16,000.

MR. PEARCE of Colorado City, Col., who has been at work on the precipitant process of securing gold, under date of the 23d, writes that the Carbon Gold Precipitant Co. will put its workings into operation at San Diego this year.

THE War Eagle, B. C., Company, up to a month ago manifested its ore as containing 2 ounces gold, 3½ ounces of silver, and 5 per cent copper. The custom house declaration now reads 2.23 ounces gold, 4 ounces silver and 5 per cent copper.

W. A. CLARK, of Montana and Arizona, is reported to have bought the refinery, copper wire works and brass works of Wallace & Son at Ansonia, Conn., for $1,000,000, for use in the United Verde mines at Jerome, Arizona. The statement is premature.

THE Ætna Consolidated Quicksilver Mining Company of California will pay its third dividend of ten cents per share, or $10,000, on May 1st. The Morning Star Mining Company of California paid two dividends on the 10th, amounting to $7 per share, or $16,800.

THE Yreka *Journal* says miners in Siskiyou are excited over the prospect of mineral lands going to the railroad company. There are men in Siskiyou, as well as in Shasta and Trinity, who have taken thousands of dollars out of ground belonging to the Government and didn't think enough of Uncle Sam to get a title to the ground that gave them riches. They are in a sweat now.

EUGENE BRADEN, director of the United States assay office in Helena, is authority for the statement that "Government statistics, covering a period of 400 years, show that there is a difference of only 1.8% in the annual net value of the gold and silver produced in the world."

MR. HANCHETT, manager of the syndicate handling the Silver Peak gold mines, Candelaria, Nevada, has completed a contract for milling machinery and lumber, and will immediately build a stamp-mill. The syndicate is composed of George Crocker and other San Francisco capitalists.

AMONG other claims to distinction the Grass Valley *Union* points with pride to the allegation that it was the first newspaper in the State to purchase a typo-setting machine, and it does not view with alarm the further statement that it will be the first to publish a newspaper in a tent.

GLASS BROS., of the Katy mine, at Basin, Mont., have paid $10,000 on the attachment claims against the company and secured an extension on the remainder of the $73,000 claims. The $15,000 in payrolls was also paid off and all attachments released, and the mine will resume operations at once.

DONALD GRAHAM, of Canada, has sued A. O. Viertong and wife, of this city, for $10,000 and six months' interest thereon. He paid that amount last August for some quartz claims in Tuolumne county, and now charges that the claims were "salted." The case is before the U. S. Circuit Court.

THE gasoline schooner, Anita, with concentrates from the Ybarra Mining Co., of Lower Cal., arrived last Wednesday from Ensenada, and was subjected to search for a $12,000 gold bar recently stolen from the company. No trace was found, and it is presumed that the stolen gold is hidden at Ensenada.

VISITING EXPERTS advise the erection of a 40-stamp mill at the Old Glory, Arizona, mine. There are two Griffin crushers of a daily 35-ton capacity there now. The mine is a big reef of quartz carrying free gold and sulphurets. The ore is said to run $17 a ton. Geo. J. Hilzinger has charge of affairs.

COLORADO has paraphrased California's sentiments, and now says: "If the world can't do without gold it can't do without Colorado. But if the Governmeat can do without silver, so can Colorado." So say we all of us. But the world can't do without gold, and the Government can't do without silver.

D. FLETCHER, of Denver, says he can treat Cripple Creek ore at $1 per ton. He pulverizes the ore in water by a rotary muller, and at the point of impact mercury in solution between positive and the negative points of a battery, catches the gold in a trough of quicksilver, and both are drawn off into a retort.

THE mining bill before the late Arizona Legislature became a law and is in force. This means a ten-foot hole on every claim located, within ninety days from the date of location. The law is intended to stop promiscuous locating of an entire county, and so held indefinitely by relocation from one year's end to another.

K. QUINE, of Riddle, Douglass Co., Or., has sold his placer mine to H. Ball of Tacoma. The property consists of a gravel bar on Cow creek, where considerable gold has been washed out with rockers. Mr. Ball will put in a pumping plant to cost $3,500. Panners are said to have made $1 to $2 a day on the ground.

THE Napa Consolidated Quicksilver Mining Company has declared two dividends of ten cents each, amounting in all to $20,000, payable next Monday. On that day the Ætna Consolidated Quicksilver will pay its third dividend, amounting to $10,000. The Homestake of South Dakota paid its 200th dividend of twenty-five cents per share, amounting to $31,250, on the 25th.

A SCHEME for the federation of Canadian mining associations is being adopted by the Nova Scotia Mining Association, Quebec General Mining Association, the Ontario Mining Association and others. It is proposed to get the mining men of British Columbia to organize and join the confederation as well. The council intends organizing a mineral exhibit in Montreal next year.

THE relief committee in Butte, Montana, after the explosion, handled nearly $44,000 at an expense of only $200. After spending $17,000 for claims of various kinds since the catastrophe, they ask to be relieved, to have all their accounts and receipts investigated, and express their willingness to turn over the remaining $27,000 to a new committee that shall make a final disposition of the surplus.

IT is feared in Montana that two of the three mineral land commissioners for each district are to be appointed outside of the State, to go to politicians defeated at the late election. The law properly executed by a competent commission familiar with the country will meet every requirement, but if the commission is composed of irresponsible men, or men in possession of no practical knowledge of the country, it will prove a failure.

AMERICAN horses are allowed to bring freight into Canada without duty being charged on the horses, but they are not allowed to carry freight out unless duty has been paid on them. The odd spectacle was recently seen of a wagon load of ore going out from the War Eagle, B. C., mine which had two horses in the shafts and two led behind. The two led behind were citizens of the United States. Those doing the work were Canadians.

PLANS for the Denver mining exhibit are being elaborated. One of these is to sink a shaft and reproduce sections of the famous mines of the continent. The workings in every particular are to be shown. Work on the shaft will begin long enough beforehand to get the mine ready to operate at the time the exposition begins. Two companies have expressed their willingness to provide all necessary sinking and driving machinery free of all cost for the advertising they would get.

THE following mining companies have recently incorporated: The Oro Fino Consolidated Mill and Mining Company—Principal place of business, Oro Fino, Siskiyou county; capital stock, $30,000; with R. J. Murray of San Francisco, Pimbrook Murray of Oro Fino, Blix Smith and Fred T. Smith of Oakland, and James B. Giffen of Sacramento as directors. The Home Ticket Gold Mining and Water Company—Principal place of business, San Francisco; capital stock, $100,000; with E. Jungerman of Columbia, Tuolumne county, A. A. Hobe, A. C. Inhaus and H. P. Dunning of Oakland, and R. A. Coleman of San Francisco as directors. The Penchblow Consolidated Gold Mining Company—Principal place of business, San Francisco; capital stock, $1,000,000; with G. M. Spencer, G. Senn, G. Grant, F. Frankenthal and W. G. Langdon as directors.

THE prices (including postage) of the publications of the California State Mining Bureau, payable in advance, to parties living outside of this State have been fixed as follows: VIth Report (1886), $1; VIIth Report (1887), $1; VIIIth Report (1888), $1; IXth Report (1890), $1; Xth Report (1890), edition exhausted; XIth Report (1892), 50 cents; XIIth Report (1894), $1; Bulletins No. 2 (Mine Timbering), 50 cents; No. 3 (Gas and Petroleum), 50 cents; No. 4 (California Fossils), 25 cents; No. 5 (Cyanide Process), 50 cents.

J. R. DE LA MAR, of Idaho, Colorado and Nevada, is in the city, and says he is ready now to buy a California gold mine, if he "can find one big enough." He will have no difficulty in that direction if corresponding requirements are sufficiently large. Capt. De la Mar has made considerable money in Idaho mines, has invented a cyanide process of his own, claiming greater speed and economy than in existing processes, and is putting in considerable machinery in Fergusoa district, Nevada, and Gillett, Colorado. He has secured one patent and has another pending.

LAST Sunday's Salt Lake *Tribune* says: "The directors of the North Fork Placer Mining Company, whose works are in Siskiyou county, Cal., held a meeting yesterday morning and decided to send a force of men under Mr. H. V. Carter, the president of the company, to California at once, to commence work and finish opening the mine. This preliminary work will take but a few weeks, as the great flume is finished and the ditch two-thirds completed. All that is necessary now is to make the connections and turn on the water. Bedrock was reached last fall, and shipping of gold will commence at once."

NONE but white men are now employed at the Hidden Treasure gravel mine, Sunny South, Placer Co. There is now a large number of men on the payroll. The running expenses of the mine for '94 were over $120,000. It is one of the many dividend paying mines of the State, of which little is heard, but which affords steady employment to many and pays its owners. On the same list may be placed the Mayflower gravel mine, three miles north of Forest Hill, in the same county, which employs about 100 men, and pays out nearly $8000 per month, and the Morning Star gravel mine, near Iowa Hill, employing fifty men, which has worked over 1000 feet of the channel at a handsome profit.

THE United States Geological Survey, under the direction of H. W. Turner, has finished a fine map of a part of the gold belt of California, which is a part of a series of maps now being prepared and which are to form a geologic atlas of the United States. The maps completed constitute "Jackson Sheet," and embrace a portion of the Sierra Nevadas, chiefly in the counties of Amador and Calaveras. These maps show the inequalities of surface, distribution of water, and the cultivated lands. They give exact height above sea level, contours, railroads, roads, trails, bridges and county lines, and are as nearly accurate as science can make them. The series comprises four different sheets, each devoted to a different subject, and will be especially valuable to miners.

THE famous old Morris Ravine drift mine, four miles from Oroville, in Butte Co., has been sold to a company of English mining men who have incorporated in London under the name of the Golden Butterfly. It consists of 1200 acres patented land, and is about as large as any one mining claim in the United States under one patent. The sale was made through Col. Frank McLaughlin, who will represent the company's operations. Considerable money was spent on the claim by its Indiana owners and still more taken out. Since the death of its principal owners, it has lain idle. Active work will at once begin on the mine. S. P. Moody will be superintendent. The local paper says many miners will be employed.

THE Alice Gold and Silver Mining Company has issued its annual report for the year 1894, in pamphlet form. The report shows that the total net silver product for the year, at the old standard value of $1.29 per fine ounce, was $455,631.08, but the discount for the year, in view of the demonetization of silver, was $231,294.86, leaving the total net product for the year $224,336.22. It also appears from the report that 116 men were employed during the year, and that the total receipts exceeded the total disbursements by $473.21. The total value of bullion shipments for the year amounted to $455,631.08, and the average price for which the silver product was sold was 62.64 cents per ounce. Thirty stamps of the sixty-stamp mill were worked during the entire period, while ten additional stamps were operated during the month of December. The gold product for the year amounted to $20,561.70.

WM. S. SMITH, who is located at Texana Mine, Wanks river, Nicaragua, writes that he left New York last October with a three-stamp mill, arriving at the mine November 10th. He immediately commenced the erection of his mill and has run it several weeks, but so far the returns are nothing. He reports the property as only a prospect. He will run the mill for another month, and if the returns are no better, will pull up stakes and return to the United States. He advises everyone to stay away from Nicaragua, as wages are low, the natives doing all the work. They work twelve to fourteen hours per day for from $10 to $20 per month, boarding themselves. He was led to believe that the company had a very rich property with lots of ore to work, but the ground is spotted and the richness of the spots is not enough to pay for prospecting to find another. Letters to and from Nicaragua are very uncertain, as the authorities closely inspect mail matter.

Personal.

LOUIS JANIN is in Grass Valley.

SUPT. OF THE MINT DAGGETT has returned from Mexico.

NELSON BENNETT, of Tacoma, Wash., is visiting Salmon river, Siskiyou Co., mines.

GENERAL MANAGER LEGGETT of the Bodie Standard Con. has returned from the East.

GEO. HOUGH, an Eastern man, succeeds Mr. Nichol as superintendent of the Comstock Tunnel Co.

E. S. HOLDEN, of the Lick Observatory, has been made a Commander of the Ernestine house of Saxony.

Electric Power Transmission.

The MINING AND SCIENTIFIC PRESS is in receipt of so many further inquiries regarding the electric plant at the Standard Con. mine, Bodie, Cal., that the easiest way to answer is to give an illustrated synopsis of descriptions by Mr. T. H. Leggett, the superintendent, who has given a clear and succiuct account in a paper read before the American Institute of Mining Engineers, in an article in the 12th report of the State Mineralogist, in an article in the MINING AND SCIENTIFIC PRESS last December, and elsewhere.

Over two years ago it was decided by Mr. Leggett and the mine directors that some better and cheaper motive power could be secured than paying $2000 a month for wood to run a 20-stamp mill, crushing and amalgamating 50 tons of ore per day. Electricity generated by water power was found feasible, and Mr. W. F. C. Hasson advised the use of a single-phase synchronous system, which was adopted. Water power was between twelve and thirteen miles away in Green creek, on the north slope of Castle Peak in the Sierra Nevada mountains, carrying 400 inches during the dry season and nearly ten times that amount during the period of melting snow.

An old ditch was cleared out, rebuilt for a length of 4570 feet, and a site selected for a power-house 355 feet vertically below its lower end. The ditch was made larger than was necessary for power purposes alone, it being intended to supply other parties when an excess of water made it admissible.

Figs. 1 and 2 give the data with regard to the ditch and pipe; Figs. 3 and 4 show the connecting flume, pressure-tank and waste-weirs. The arrangement of the screen adopted, while it occasions a loss of head of a couple of feet, was deemed necessary where anchor and slush ice form during cold weather.

The pipe is of large diameter, in order to permit subsequent enlargement of the plant, and also to reduce loss of head by friction. It is fitted with three 2½-inch air valves, to prevent collapse in case of sudden rupture, and is anchored at proper intervals with straps of 1¼-inch round iron. The slip-joints extend to a coupling to the armature shaft of a 120 K.-W. A. C. generator. The accompanying illustrations show the generator and water wheels in operation, and the generator switch-board at the power-house. The two similar sockets on the motor switch-board. The small converter in the upper middle of the switch-board has a transforming ratio of 30 to 1. Its primary coil is attached to the main-current wires

Fig. 1.

STANDARD CONSOLIDATED MINING COMPANY
Water and Electric Power Plant,
at Green Creek,
Near Bodie, Mono County, California.
Scale: 1 Inch = 1800 Feet

DATA:
DITCH 4560 ft. long, section, , grade, 0.2 ft. per 100 ft.; capacity 3,500 miners' inches.
PENSTOCK 12 ft. x 12 ft. x 6 ft.; capacity, 540 miners' inches (1.6 cubic ft. to the inch.)
PIPE LINE 1,571 ft. long,
1555½ ft. of 38 inch diam., No. 12 Iron C and S joints.
502¼ " " 30 " " 12 " " slip joints.
413 " " 22 " " 10 " "
RECEIVER Drum of John Steel, 9'6" x 20", with 18" Gate Valve, Safety Valve, etc.
EFFECTIVE HEAD 350 feet.
WATER WHEELS: 4 24-inch special Pelton Wheels, 240 H. P. Max., 865 Revs.
GOVERNOR One Doolittle Governor; one No. 2 Pelton Motor, 2,410 Revs.
DYNAMO: One No. 2, 120 K. W. Westinghouse A. C. Generator, coupled direct to wheel-shaft; E. M. F., 3,530 volts
EXCITER: One Type G Exciter with rheostat 2,050 Revs., driven by One No. 2 Pelton Motor, 910 Revs.
COST OF WATER POWER per H. P., $46.00.

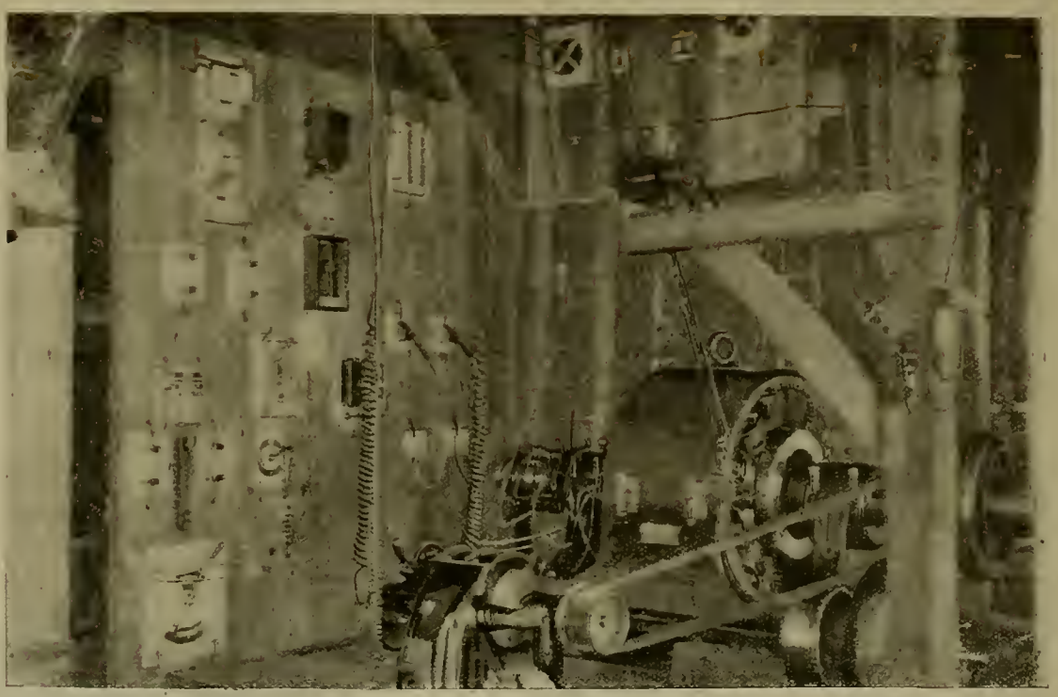
see that all is running smoothly. Any change in tone of the hum of the dynamo warns him at once of a change of conditions, the tone rising or falling according as the speed increases or diminishes, though ever so slightly.

To insure the all-important factor of constant speed, a technometer, registering to 1200 revolutions, is belted to the water wheel and dynamo shaft. Its dial faces the water wheels, so that the attendant at the valve lever can readily maintain a uniform speed during the operation of "synchronizing" the motor and starting the mill, at which time the load is constantly varying.

In front of the jaw switch on the switch-board there will be noticed, in the view of the latter, a steel spring, and also two cords attached to the handle of the large rheostat. These cords are led around the side of the building to the attendant's place at the valve lever, as is also the one that releases the catch of the spring. A pull on these cords opens the exciter main-circuit instantly, and puts in the entire resistance box, thereby "killing" the fields of the generator and preventing any dangerous rise in electro-motive force, should the load be suddenly thrown off by a break in the wire-line, or other accident causing a sudden increase in the speed of the armature shaft. This arrangement was devised by Mr. Leggett, before the speed of the governor



GENERATOR SWITCH-BOARD AT POWER-HOUSE.

Generator in operation; exciter in foreground; choke coils and gap-lightning arresters on separate board.

POWER-HOUSE AT GREEN CREEK.

was trebled, the constant-resistance fly-wheel was put in and other changes were made, giving more sensitive and perfect control of the water power; and it is left in place because it might still be of use in case of emergency. The power-house is lit by a small 10 light converter attached to the generator-circuit, and when the generator is not in operation, by current from the exciter. Above is given an illustration of the power-house at Green creek.

The length of the line is 67,760 feet, or 12.46 miles. The poles are of round tamarack timber, 21 feet long, 6 inches in diameter at the top, set 4 feet in the ground; poles 25 feet long being used through the town, and along the line wherever there is danger of deep snow drifts. They are placed 100 feet apart, and fitted each with a 4 by 6-inch cross-arm, boxed into the pole, and held by one bolt and one lag-screw. The object of chamfering the ends of the cross-arms is to leave less room for the lodging of snow under the insulator.

The line crosses extremely rough country, not 500 yards of which is level beyond the town limits. Most of the ground is very rocky, over 500 pounds of dynamite being used in blasting the pole holes. Accompanying are views along the line in summer.

The wire is No. 1 gauge, soft-drawn bare copper, and is attached to standard, double-petticoat, deep-groove glass insulators. The distance between the wires is 3 feet 8 inches, and there are over 16.5 tons of copper in the line. The only objection found to the iron pins is their liability to be withdrawn from the cross-arm during a gale of wind, whenever there is an upward pull on the wire. To obviate this a number of pins were drilled with an ⅛-inch hole near the end, and in all such places these were used, and held firm by driving a wire nail through them.

The wire was first attached to the insulators by tie-wires of No. 10 galvanized iron wire. Later it was found advisable to insulate the line wire at the insulators, and for this purpose ordinary sheet rubber ⅛-inch thick, such as is used for gaskets, was cut into strips 1.5 inch wide and 12 inches long. These were wound spirally about the wire and held in place by two close wrappings of Manson's tape. The whole was then well daubed with asphalt paint, and the insulated wire re-attached to the insulators by tie wires of No. 6 weather-proof copper wire.

The line crosses a number of very steep ridges (from 300 to 800 feet in height), and on these the wire necessarily pulls heavily on the top pole, and especially on its pins and insulators. In all such places the ordinary double-petticoat insulators were replaced by the large Pomona insulator, on which the wire is carried in a groove across the top, and its weight is therefore directly down upon and in line with the center of the pin.

(To be Continued.)

SUMMER VIEW ON POLE-LINE, LOOKING EAST, TEN MILES FROM BODIE.

SUMMER VIEW ON POLE-LINE, LOOKING WEST, TEN MILES FROM BODIE.

THE Juneau *News* says the Berners' Bay mill is running twenty stamps by water and steam on high-grade gold ore from the Comet mine, which produces galena ore carrying gold.

Rix Air Compressors.

(Continued from page 193.)

pressor piston is under full pressure. It has a Meyers cut-off also to add to its economy. No beat from the engine is radiated to the air cylinder on account of its position.

This machine will pay for its increased cost in a short time in fuel saving, and will require little attention beyond that required for proper lubrication. The air flows to the cylinder through the piston, in which are four small valves, the springs for which can be renewed in not to exceed one minute when necessary.

The eugineering public is awaiting with considerable interest the completion of the 700-horse power compressors, for compressing air to the unusual pressure of 2000 pouuds per square inch, that Mr. Rix has designed, and which the Fulton Engineering and Ship-Building Works are now installing at Fort Winfield Scott, for operating the three pneumatic guns now being erected tbere.

Each compressor is triple stage, that is to say, the air is first compressed in two initial double-acting cylinders to about seventy-five pounds per square inch, then passed through a cooler composed of copper pipes, submerged in cold water, then taken into the intermediate single-acting ram and compressed to about 400 pounds to the square inch, thence through another cooler composed of smaller copper pipes, thence to the high-pressure ram, where it is compressed to 2000 pounds per square inch, and from thence through a final cooler of still smaller copper pipes to the storage reservoirs, which are a bank of steel tubes, twenty-four in number, thirty feet long, and having a diameter of sixteen inches and thickness of $\frac{13}{16}$ of an inch; the heads are welded in solid. It is very difficult to hold air at this pressure, and a small leak would soon materially detract from the capacity of the compressors. Special methods of making joints are employed, and all flanges, bolts, pipes, etc., are of a seemingly unnecessary proportiou. The engines to do this work are four in number, twenty inches diameter by twenty-four inches stroke, arranged with Meyers' cut-off. Tbere are four 72×16 boilers, arranged for forced draught, the air being forced into the furnaces by two steam Sturtevant fans, each having outlets twenty-two inches in diameter. The water for cooling the compressed air and for boiler purposes will have to be pumped from the old Spring Valley flume, about 2000 feet distant aud 300 feet below the level of the engine house. This will be doue either by electricity or compressed air, as may be deemed expedient.

Some careful experiments will be made with this plant to determine some questions hitherto unsettled and which will be of considerable advantage to engineers. Much tbought is now being given tocompressed air, as a means for power transmission, and eminent authorities are sanguine that it will shortly prove more efficient for general purposes than electricity or steam. The immense power plants in Paris and Birmingham show a marvelous efficiency and an ever-increasing demand from power users. Compressed air offers the very reasonable advantages that, the supply is boundless, it is perfectly elastic, easily transmitted, the exhaust from the motors is harmless, and it can be used for an endless variety of work.

Colorado Mining Stocks.

Writiug from Colorado Springs, Colorado, under date of March 25th, F. H. Pettingell, among other things, says :

This is a period when many anuual meetings of mining companies will be held. The owuers of stocks should carefully direct their interests and show some discretion in giving proxies, and it would be better by all means for them to attend these meetings if possible.

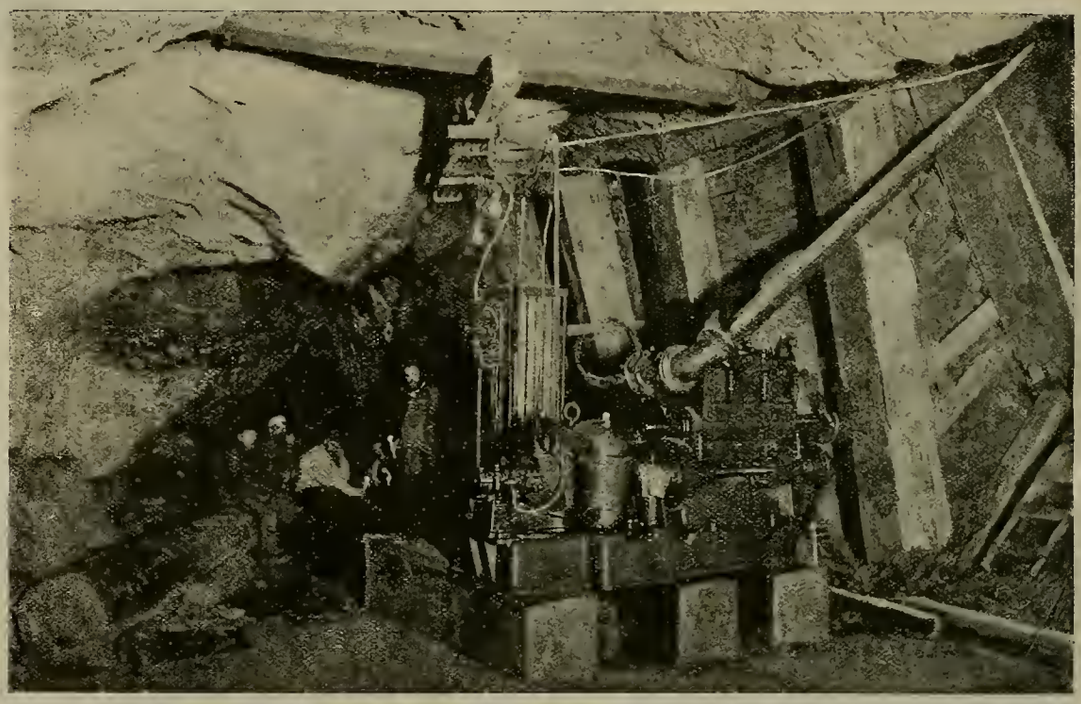
If the directory of the company has conducted the affairs of the company in a questiouable manner during the past twelve months, steps should be taken to accomplish a change. This can only be done by the uuited efforts on the part of the stockholders. Judging from the manner in which the affairs of certain companies have been conducted, any change would be a decided improvement.

There are too many stocks speculated in on this market, whose management is rotten to the core. If this is to go on uninterrupted, the probable result is too plain for comment. The business is, in my opinion, daily becoming more legitimized by many reforms, and these, of course, materially affect its permanency.

Electricity in the Gover Mine.

In several instances electric motors are in use underground in California mines. Herewith is illustrated an electric pumping plant on the fifth level of the Gover mine in Amador Co. Superintendent McCall says:

"Two triple-plunger Dow pumps are used—one with six-inch plungers raising $12\frac{1}{2}$ miuer's inches of water 341 feet vertically, and one with five-inch pluugers raising 11 miuer's inches of water 208 feet vertically. An Edison dynamo, No. 16, of 50-horse power capacity is used, and run at a speed of 820 revolutions per minute, tbe voltage being 220. Sprague motors are used. The one working the larger pump is run at a speed of 1000 revolutions per minute, giving 20-horse power; and tbe otber is run at a speed of 1250 revolutions per minute, producing 15-horse power. The voltage in the motors is the same as that of the dynamo. Copper wire $\frac{5}{16}$-inch in diameter transmits the power from the dynamo to tbe motors, a distance of about 1700 feet—1000 feet on the surface, and 700 feet down the shaft. The wires cause no trouble whatever in the shaft, retimberiug even being done without stopping tbe pumps. The shaft is quite wet in places. The pumps have run three years and four months, pumping during that time 50,000,000 gallons of water. The armature of the dynamo burnt out once, owing to injuries received in shipment, the core being sbifted. The commutator of tbe dynamo is turned down about once a year. The motors are connected with the pumps by gearing. Rawhide pinions are used on the armature shafts. The rawhide pinions last a year, and are more reliable and more satisfactory than those made of bronze. With the motors, the only precaution taken agaiust dampness is a thorough coat of paraffine paint. The smaller motor was run at one time for several hours with the field piece half way under water."



ELECTRIC PUMP ON FIFTH LEVEL, GOVER MINE, AMADOR COUNTY.

Obituary.

Captain D. l. Ezekiel, a widely known mining man of Denver, died in that city last Saturday.

William S. Pierce, manager and chief owner of the Petaluma Electric Light & Power Company, owner of the Pierce Telephone Company, president of the California Dairymen's Union, and one of the most wealthy and prominent citizens, was instantly killed by contact with one of the wires last Saturday.

John Timmons, one of the original builders of the South Yuba canal, and once a millionaire, died at the city almshouse last week. He was associated with the Comstock people twenty-five years ago, but lost his money in speculations. In the early fifties he was associated with J. S. Green, the Husseys and others in developing Nevada county's resources, building the Remington Hill ditch and the South Yuba canal. He sold his mines to Alvinza Hayward for a large sum, but sunk it elsewhere.

The annual report of the Bell Telephone Company shows the expenses of the company for the year to be $1,724,459.87, and tbe net earnings $3,123,789.05. Tbe surplus account December 31, 1894, showed $2,151,011.61. The long-distance company shows an increase in gross earnings of 13.4%, the amount for 1894 being $1,011,061.82.

A California Stamp Mill.

Many devices have been invented for crushing ore, but thus far the California stamp mill remains at the head of the procession. Tbese mills are built in batteries, usually of five stamps each, and ordinarily at first the mill consists of one battery only, but is so arranged that additional batteries may be placed in position when the mine is found to warrant the expenditure. The price of the mill is usually estimated at so much per stamp, usually costing about $1000 per stamp by the time the mill is ready to begin crushing ore. Of course, the price depends upon the difficulty attendant in getting the mill to the mine and also on the weight of the stamps, which runs from 250 to 950 pounds each. A medium-weight stamp, about 750 pounds, is most commonly used and is suitable for crushing almost any class of ore. Tbis estimate of so much per stamp includes the boilers aud engines, amalgamating plates and all that is necessary to haudle free-milling ore.

Each battery consists of a large integral cast-iron mortar having a rectangular bed, within which the "dies" are arranged. Each die consists of a square base having upon its top a cylindrical projection which is just tbe diameter of the stamp and is arranged to receive the blow from its respective staup. A layer of sand or ore is placed in the bottom of the mortar before the dies are placed in position, in order to form a cushion to prevent the blows from the stamp breaking the mortar. The mortar is cast with a heavy frame above it, somewhat like a basket with an exceedingly heavy handle, and in this frame are provided guideways in which play tbe stems of the stamps. Still above this frame is another heavy wooden frame, iu which play the upper ends of the stamp stems. Between the two frames is arranged the cam shaft, which is provided with one cam for each stamp. These cams are shaped somewhat like a very heavy, strong sickle, and are from eight to fourteeu inches in length. The handle end is provided with an opening, through which tbe cam shaft passes and a key secures it rigidly in place.

The stamp stems are round shafts of iron, and in a battery of 750-pound stamps the stems are about four inches in diameter. To the lower end of the stem is keyed a cast base, having a socket in which fits the stem of the stamp "shoe," which is from six to teu inches in diameter and about one foot in length when new. This shoe is also keyed in the socket so it can be easily removed when necessary. Upon each stamp stem, above the cam shaft and in the path of its respective cam, is keyed a collar called a "tappet," and at each revolution of the cam shaft each cam engages with its respective tappet and lifts the stamp until the cam passes from under the tappet and lets the stamp drop. The cams are arranged spirally around the shaft so that the stamps are raised aud dropped iu regular succession, and not all at once.

The rear of the mortar is closed by a thick, wooden plank which is wedged tightly in grooves in the mortar, while the front is closed by means of a screen of wire cloth or of slotted sheet metal. These screens are of different degrees of fineness, running from 40 to 120 openings to the inch, and the fineness of the screen depends upon the character of

the ore. When the gold is coarse a forty-mesh screen will answer, but if the gold is fine a sixty or eighty-mesh screen will be required. Very fine gold may require a 120-mesh screen, but this is unusual. The screens are fastened on frames which fit into grooves in the mortar-box, and are wedged firmly in place by iron wedges. Strips of blanket are tacked along the edges of the frame so that when in place the joints will be water tight, and all the matter which escapes from the mortar-box will have to pass through the screen.

The "drop" of the stamps that is, the distance they fall—is regulated by adjusting the tappets on the stamp stems. A seven and one-half inch drop is enough to crush ordinary quartz, but the hard quartz sometimes takes a drop of nine inches or more. Each stamp is arranged to drop from forty to ninety times per minute, dependent upon the distance it falls. If the drop is nine inches and the speed ninety times per minute, the cam will usually catch the tappet before the shoe hits the die, and of course the ore will not be crushed if this is done, the cam receiving the full force of the blow.

The ore is placed in a large hopper, which has its lower end closed by one side of a large, horizontally arranged iron plate, which is connected by means of cog-wheels; a ratchet and an arm, with a plunger which extends upward far enough to be struck by a tappet on one of the central stamp stems. This plunger can be regulated so that the tappet will only strike it when the stamp has just sufficient ore beneath it to keep it from "pounding iron," as it is termed when the shoe hits upon the die itself. When the tappet hits the plunger the plate is rotated an inch or two and the ore is carried against a scraper, which causes it to fall from the plate into the mortar-box; when too much ore gets beneath the stamp, the tappet does not strike the plunger and no more ore is fed to the stamps until enough has been crushed and washed from the mortar to allow the tappet to again strike the plunger.

In front of the mortar is arranged the "apron," an amalgamating plate, upon which is discharged all the crushed ore which passes through the screen. Amalgamating plates are also arranged in the "battery," as the inside of the mortar box is termed. These amalgamating plates are of copper, about three-sixteenths of an inch thick, and are plated with silver. Before being placed in position each plate is "charged" by being coated with quicksilver, which clings to the plate in a thin sheet.

Below the "apron" is arranged a long sluice, which sometimes has its bottom covered with amalgamating plates over which the ore all passes on its way to the "slum" pond. If the ore is hard to work, it is common to run it through "mullers," or larger cast-iron basins, each having a rotary grinder arranged therein.

When everything is ready the mill is started. The stamps are all "hung up," or, in other words, the tappets are held out of reach of the revolving cams by means of pivoted uprights which are arranged to sit beneath the tappets. In starting the mill the engine is set going and the cam shaft revolves, but as long as the tappets are supported by the pivoted uprights the cams revolve freely. To set the stamps in motion the millman takes a well greased wedge, which is covered on both sides with leather, inserts it beneath the tappet of the first stamp, and as the cam comes around it strikes the wedge and lifts the tappet from the upright, which is then swung to the rear out of the way, and the stamp is permitted to drop. The stamps are all released in turn, and in a few seconds the mill is in operation, and a deafening roar fills the building and reverberates from the hills. A stream of water is kept constantly flowing into the battery, and as the stamps pound the ore to powder it mixes with the water, and that ore which is fine enough passes with the water through the screen and down the sluice to the "tailing" or "slum" pond. Nearly all the free gold is amalgamated by the quicksilver on the plates in the battery, but what little is not catched on the "apron" plate, and, if the ore is rich, soon small, hard, white lumps begin to appear on the apron. When this occurs the millman knows that the quicksilver on the plates in the battery has taken up all the gold it will hold, and he begins to "feed the battery" by throwing in a small quantity of quicksilver to amalgamate the gold in the battery. The amalgam gathers on the battery plates, and as soon as hard amalgam begins to show on the apron more "quick," as it is called by the millmen, is fed to the battery.

If too much "quick" is fed to the battery, it splashes out through the screen and softens the amalgam on the apron until it runs freely; and when this occurs, no more "quick" is fed to the battery until the amalgam on the apron again gets firm.

The richness of the ore can be pretty accurately gauged by the amount of "quick" it calls for. In ordinary free-milling ore two ounces of "quick" will amalgamate one ounce of gold. The "quick" is fed by means of a small spoon, which holds about as much as a child's thimble, or one ounce of "quick."

Each stamp should crush one ton of ore in ten hours. If the battery takes ten ounces of "quick" an hour, the millman knows that the ore crushed during that time contained about five ounces of gold, worth usually about $17 per ounce; thus the ore would mill about $170 per ton.

All gold bullion is not of the same fineness. That is to say, as the gold comes from the ore it is mixed with baser metals, such as silver and copper, and the value of the gold bullion depends upon the amount of base metal it contains. Copper and silver will amalgamate as well as gold, so it sometimes happens that the battery takes lots of "quick," but the amalgam will be of slight value. It is impossible to give correct figures on the value of the ore until the bullion is assayed to determine the purity of the gold.

As each cam lifts its stamp, it partially rotates it by its action against the tappet, so that the stamp-shoes are constantly turning around and caused to wear evenly. As the shoes and dies wear away from the constant abrasion of the hard quartz, the stamps are lowered by raising the tappets upon the stamp stems. A stamp shoe a foot long, when new, will, in a month or two, wear down to one-half that length.

If no accidents occur, the mill is kept in operation until it is decided to make a "clean-up" of the amalgam. When this is decided upon, the stamps are "hung up" by a reversal of the operation by which they were set into action.

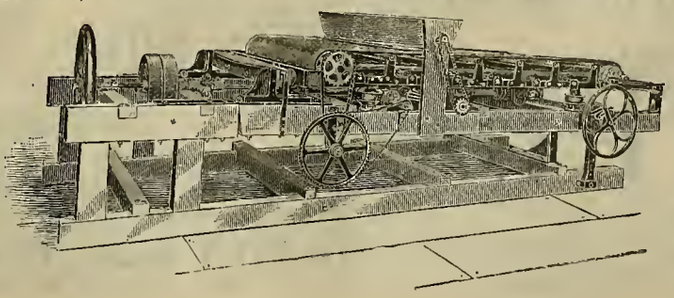
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
including prepared canvas belt 1 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1895.
THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. E. BALLOU, Propr. Ballou Reduction Works.

Scientific Progress.

A Tubular Frame House.

M. Caron, of Chamouuix, has just built a most peculiar house, for which he claims, first, a constant temperature and incideutally strength, durahility, comfort and beauty. The change of temperature in the valleys of this mountainous region is frequent and sevcre, and the buildiug of such a house was prompted by the severity and instahility of the climate. Mr. Caron first put up a frame of steel water tubing, allowing continuous circulatiou to a stream of water. Around this frame he put up his house in the ordinary way, the entire structure being a very pretty specimeu of the early Italian renaissance. The peculiarity is that all floors and ceilings are likewise crossed and recrossed by the water pipes. The water, after passing through the horizontal tuhes first, that is uuder the floors and ceilings, passes through the vertical tuhes until all have been goue through. In summer, spring water, fresh as is only the water of thc snow-capped Alps, circulates under pressure through the network of tubes, cools off thc walls, and, after having run its coursc, flows off considerahly warmer than when it entered. But in its course it has absorbed much heat, which it carries away. During the long and severe winter thc water, eutering through the basement, is first heated to nearly 100°, and then forced through the tubing. Of course, much of the heat is left all over the house, and at the outlet the temperature of the water is about 40°. The speed of the circulatiou of water can be regulated so as to allow the fixing of a certain temperature for the house, which is equal throughout. The house has been put to a practical test through the last eight months, aud has stood the trial well. The builder claims for it cheapness, solidity and elasticity, giving it immunity against earthquakes. The housc measures about 6000 cubic yards and weighs 120 tons, or 36 pounds per cuhic yard iuclosed. It is fireproof, having running water iu every room, and fire can he drowned out in a remarkahly short time.—La Nature.

Parts That Do Not Grow Old.

In his work on the senilc heart Dr. Balfour tells us that there are two parts of the human organism which, if wisely used, "largely escape senile failure." These two are the braiu and the heart. Persons who think have often wondered why brain workers, great statesmen, and others, should continue to work with almost unimpaired mental activity and energy up to a period when most of the organs and functions of the body are in a condition of advanced senile decay. There is a physiological reasou for this, and Dr. Balfour tells us what it is. The normal hrain, he affirms, "remains vigorous to the last," and that "because its nutrition is specially provided for." Ahout middle life, or a little later, the general arteries of the body begin to lose their elasticity and to slowly but surely dilate. They become, therefore, much less efficient carriers of the nutrient hlood to the capillary areas. But this is not the case with the internal carotids, which supply the capillary areas of the brain. On the contrary, those large vessels "continue to retain their pristine elasticity, so that the blood pressure remains normally higher than within the capillary area of any other orgau in the body. The cerehral blood paths being thus kept open, the brain tissue is kept better nourished than the other tissues of the body." Who is there amoug those who have reachcd or passed middle age that will not he rejoiced to find such admirahle physiological warrant for the helief that the brain may continue to work, aud even to improve, almost to the very last hour of life?

As soon as Thomas A. Edison can find the time, he means to learn something about argon, the newly discovered gaseous constitute of the atmosphere. Mr. Edison not only helieves in the discovery of Lord Raleigh and his co-workers, but thinks it probahle that further experiments will disclose other uew elements in the air. "To tell the truth," said the electric wizard, "the discovery of argon is a fresh evidence of how little we know even of the commonest matters. The air has heen analyzed over and over again for half a century without suspecting that it held any new elements." Mr. Edison explained that his investigations concerning his incaudescent lamp showed him phenomena which could only he explained on the hypothesis of a new element. But he was unable to say whether argon was responsihle for those phenomena.

Animals are like the bright and fragrant flowers of plants—when their function is accomplished, they wither and perish. The husiness of the auimal seems to be, not to live its own life, but to reproduce its own kind, and the term of life at its disposal is adjusted accurately to the special difficulties of this purpose. Death comes as soon as possible after the due number of successors has been produced, in order that each species may always he represented by a full tale of young and vigorous individuals. Natural selection acts like a contractor who has undertaken to keep a window box gay with fresh blossoms—each plant must he removed almost before its flowers fade.

The signal service of the Uuited States is founded on the text in Ecclesiastics: "All the rivers run into the sea, and yet the sea is not full." Commodore Maury writes that it was hy thinking on the meaning of this assertion that he first got at the central idea of what is now the growing science of meteorology.

Prof. Gilbert, the geologist, has come to the conclusion that the huge hole in the ground known as the Diablo cauyon, in Arizona, marks the place where a large meteor once struck the around.

GREASE CUPS

"SUCCESS BRINGS SUCCESS."

Did you ever stop to think what this means? Did you ever notice how the "successful" firm transacts its business? It does it through "successful" channels. The Lunkenheimer Company is said to be a "successful" firm; that their specialties are a "success;" that the name "Lunkenheimer" on Brass Goods means "success." You can judge for yourself by sending for their new Catalogue. No steam user should be without one. Gratis upon request. We don't want all your trade, only a share.

WE HAVE COME TO STAY.

THE LUNKENHEIMER COMPANY.

Mechanical Progress.

The Wage Worker in Germany.

Vice-commercial Agent George H. Murphy, writing from Luxemburg to the State Department, gives some facts germane to present economic discussion. He finds that the standard of wages is almost the same in Luxemburg as in Germany. Generally speaking, the average earnings of ordinary workmen amount to less than $200 per annum. Women earn about half as much as men. The average wages of miners and foundry hands is less than $1 a day. The average annual salaries of primary-school teachers are $224 for males and $179 for females. A very large majority of the officials and employes of the Government earn less than $400 per annum.

On the other hand, speaking generally, the necessaries of life cost as much in central Europe as they do in the United States. A workman's expenditures for clothing and rent may possibly be somewhat less there than in the United States, but in the town of Luxemburg coal costs $7 per ton, eggs twenty-one cents per dozen, rye flour three cents per pound, wheat flour five cents per pound, sugar eight cents per pound, butter twenty-five cents per pound, beef nineteen cents per pound, veal and mutton sixteen to twenty cents per pound, fresh pork twenty cents per pound, and smoked pork twenty-three cents per pound.

WOOD-PULP PIPES, now coming into vogue for special uses, are manufactured by a very simple process. The pulp, says the *Scientific American*, is agitated with water and rolled upon a tube, and, after being thus wouud to a sufficient thickness around the tube, and the extra amount of water drained away, it is placed on end and the interior mold is withdrawn, leaving the wood-pulp tube, which is held on suitable supports and dried until the water is evaporated. The further process consists in dipping it into a very hot solution of asphaltum and other materials, which penetrate the whole substance; the ends are then squared up and the threads cut, or taper finish is made in the usual manner of wrought-iron pipe. This material, when finished, possesses high electrical resistance, rendering it suitable for underground conduits for electrical wires, and, as a non-conductor, it is free from being impaired by electrolytic action from earth return currents, which have become such a serious factor in impairing the water and gas pipes in cities where the street tram cars are propelled by electric motors using earth return currents; its resistance to acids and alkalies fits it for use in chemical works, and as a non-absorbent of water it is free from any difficulties due to expansion and contraction. The bursting strength of the tube is said to be from 150 to 250 pounds per square inch, according to the size.

IN speaking of the tendency of boiler-plates to crack, *The Locomotive* states that cracks frequently start from the edge of the plate opposite a rivet hole, in the girth joint that comes over the fire. Such cracks are often due to distress at the joint arising from an improper arrangement of the feed-pipe, for if the comparatively cold feed-water is discharged on or near the fire-sheet it chills the shell in that vicinity, and produces a powerful local contraction of the metal, which is quite sufficient to start the joints, or, under some circumstances, to even crack the solid plate. But whatever the cause of the cracks, they are likely to first appear at the edge of one of the fire-sheets and to extend gradually inward. Often they are stopped by running into the rivet hole and do not extend farther. Frequently, however, they run past the rivet hole or cross it and extend into the sheet on the farther side of it. It then becomes very important to check their further progress. This may often be done by drilling a small hole through the sheet at the very extremity of the crack. This hole may afterward be filled with a rivet, or it may be tapped and filled with a screw plug.

To Clean Machinery.

A method of removing sticky deposits of grease and dirt from parts of machinery by means of soda lye is quite extensively employed in England. To 1000 parts by weight of water are taken about 10 or 15 parts caustic soda and 100 parts ordinary soda. This mixture is boiled and the parts of the machinery to be cleaned are placed in it, when all grease, oil and dirt are quickly loosened. It is then necessary to wash the metal and dry it well. The actiou of the lye is to form with the grease soaps soluble in water. To prevent the lubricating oil, etc., hardening upon the parts of the machinery when in use, it is necessary to add a third part of kerosene, and it is well, also, to oil with kerosene from time to time.

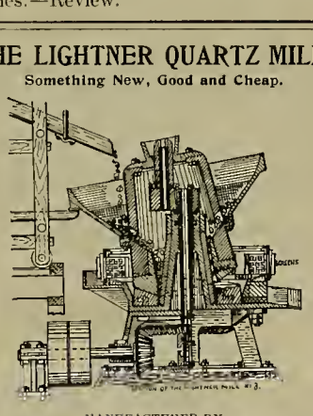
Surpassing Edison and Tesla.

W. W. Felts of 2228 O street, Sacramento, has a proposition iu eleetric lighting that is comprehensive. He elaims to have succeeded in developing a continuous electric light from a primary battery and that his battery is a perfect electrolite aud polarizer combined. He invites persons interested to inspect his thirty-two candle power incandescent lights at his residenee. But he refuses to allow anybody to inspect his battery, which is in a sealed box.

Electricity is Dutiable.

Comptroller of Canadian Customs Wallace has decided that electricity comes under the head of unenumerated articles, and consequently bears a duty of twenty per cent. The question arose over a proposition to transmit power from the American side of Niagara falls to surrounding Canadian cities.—Review.

THE LIGHTNER QUARTZ MILL.
Something New, Good and Cheap.



MANUFACTURED BY
WM. H. BIRCH & CO.
Also Manufacturers of
Cary Steam Pumps, All kinds of Mining Machinery, Boilers, Engines, Ore Buckets, Ore Cars, Cages, Hoists, etc.
119 Beale St., San Francisco.

PLACER
Amalgamators,
Dredgers,
Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.

Highest possible Gold yield insured.

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.

Crushing, Pulverizing, Concentrating and other machinery also built.

Investigation solicited.

JAMES H. LANCASTER, Patentee,
39 CORTLANDT ST., NEW YORK.

Professional Cards.

A. H. RICKETTS, Attorney-at-Law,
Mining Patents and matters before the Land Department a Specialty.

PRACTICAL ENGINEERING SCHOOL,
205 Goodnough Bld'g, Portland, Or.
Civil, Electrical, Steam, Mining, Assaying. Full charge of plant taught. Circular.

The Evans Assay Office.
W. N. JEHU, - - - Proprietor.
Successor to Jehu & Ogden.
628 Montgomery Street, San Francisco.
Rooms 46 and 47 Montgomery Block.
Ore Assays, Analyses of Minerals, Metals and their Alloys, Etc.
LESSONS GIVEN IN ASSAYING.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering.
Surveying, Architecture, Drawing and Assaying.
723 Market St., San Francisco, Cal.
OPEN ALL YEAR.
A. VAN DER NAILLEN, President.
Assaying of Ores, $25; Bullion and Chlorination Assay, $25; Blowpipe Assay, $10. Full Course of Assaying, $50. Established 1864.
Send for Circular.

JOHN W. GRAY, Engineer and Surveyor.
Examination, Surveys, and Reports upon Mines, Drainage, Tunnels, etc.
Development of water for mining and domestic use, irrigation, and the production of power. General Surveying of all kinds, and plans prepared. Construction work superintended. Correspondence solicited.
Res.—923 Linden St., Oakland, Cal.

EDWARD S. COBB,
Mechanical Engineer and Expert.
Tests and Estimates for the improvement of Pumping, Power and Hydraulic Plants.
Will supervise the Construction, Shipment or Erection of Machinery. Will make Drawings, Estimates or Specifications.
Prices obtained for machinery of every description. Twenty year's experience.
123 California St., San Francisco, Cal.

GILES OTIS PEARCE,
Mineralogist and Metallurgist.
708 Colorado Avenue, Colorado City, Colo.
Will examine Mines, Ore Bodies, Mineral Belts or Zones, and make written Mineralist Reports, fees for which made known upon application for services. I make my own assays and select my own samples when examing mines. Eighteen years' experience. Analysis of water and soils.

Almarin B. Paul, M. E.,
Mining Operator,
ROOM 5, CROCKER BUILDING.
Cor. Market and Montgomery Sts., San Francisco.
Will give attention to the sale of and reporting on RELIABLE Mining Properties, or the procuring of suitable Machinery for interest in Developed Mines.
Plans and Estimates made for IMPROVED CYANIDE PROCESS PLANTS, and competent instruction for working the same on a large, practical scale.

Nevada Metallurgical Works,
No. 23 Stevenson Street,
Near First and Market Sts., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUSPENDED.—*Republican:* The gravel claim at Pine Grove, commonly known as the Wheeler mine, has suspended. They finished the first clean-up, which it is reported was sufficient to pay the expenses involved in putting the property on a good working basis, also the running expenses. Another payment on the bond became due this month, and they concluded to quit. Tbey paid $500 on the bond at the outset, so that sum represents their loss. The property was worked in a crude fashion, and it is thought that if it paid expenses under such conditions, there is little above that with proper management it would pay a handsome profit.

SOLD TO CHICAGO MEN.—The Bell Wether claim, a continuation of the Zcila ledge, has been sold to Messrs. Underwood and Snediker, of Chicago.

THE ANITA MINE.—A new Dow pump has been put in, which controls the flow of water. The miners bave all returned to work—three shifts of eight hours each.

Butte.

MAGALIA.—*Mercury:* The most active work at present being done is at the Lucky John mine by Gorrel & Ballard of San Francisco. Tbis is the mine that was owned hy J. D. Williams and N. A. Harris. Tbey are running for the channel hy tunnel, and are now in 1200 feet, and gravel bas been struck. From fifteeu to twenty men are employed.

At the Aurora an incline is heing put down which has reached a depth of 160 feet, and it is estimated tbat it will have to be put down nearly as much farther before the channel is reached.

At the Pershbaker an immense power plant is being put in sufficiently large to handle the water, together with air compressors. Parry & Merry, who have been working for six or seven years on a searcb for tbe main channel wbich underlies that country for a distance of thirty miles or more, are now to a depth of 700 feet, and they believe that success is abont to crown their efforts.

Calaveras.

THE BACHMAN MINE. — The old Bachman mine at Fourth Crossing, idle for fifteen years, bas been bonded by Ford Bros., who will put on a force of men developing.

THE IDEA REVERSED. — *Citizen:* Recent transactions at Murphys go to show that instead of the mine holder wanting a thousand dollars for a hundred dollar mine, it is capital tbat wants a thousand dollar mine for one hundred dollars.

TO BE EXTENDED.—Louis Fahl has taken a contract from the Buckhorn Mining Company, of Napa, Cal., to extend the tunnel in the Buckhorn mine.

BOUGHT A HALF INTEREST.—C. A. and E. C. Rudorff have bought a half interest in the Old Stiff gravel claim on Balaklava Hill, uear Vallicita.

El Dorado.

QUARTZ CLAIM LOCATED.—*Democrat:* Ed Stafford and Jas. H. Blakeley have located a quartz claim near Grizzly Flat. Fifty tons of ore from this claim have been worked in a stamp mill and paid $4 per ton in free gold.

Inyo.

ASSESSMENT—WORK RESUMED.—An assessment of ten cents per share bas been levied hy the Owens River and Big Pine Canal Company, delinquent April 6th.

Work has been resumed on several mining claims at Cerro Gordo.

Mariposa.

THE HEATON MINE.—There are now fourteen men employed at the Heaton mine.

Nevada.

THE BULLION AND IONE.—Tbe Bullion and Ione mines are to be worked again. Mr. Geo. Mainhart will be the superintendent.

THE SPANISH MINE.—Thirty men are now employed at the Spanish mine. Tbe new ten-stamp mill is crushing ore from the shaft. No stoping is yet being done. Mr. A. L. Begbie is superintendeut.

WORKING PLACER GROUND.—*Tidings:* M. Bates and E. Eagye are erecting a derrick and making other preparations for working that portion of Gold Run creek from Byrne's planing mill to Deer creek.

BELLE OF FRANCE.—*Tidings:* The lower tunnel at this mine has been reopened and retimbered for a distance of 360 feet. It was expensive and dangerous work. The ore chute was struck a distance of 405 feet from the mouth of the tunnel and 200 feet vertical from tho surface. The vein is 20 feet wide, and is well mineralized. It is enclosed by greenstone and slate walls. A mill test shows results ranging ahout $4.50 per ton in free gold, which, with the sulphurets, will run the value up to $10 per ton. Tunnel No. 1, heing 700 feet south of the point where the vein was encountered in development work done in tunnel No. 2, shows the ore hody to he large and extensive. The Belle of France gives promise of being a valuable property.

THE BOSS MINE.—W. L. Morris of the Boss mine denies the report that the mine is about to be sold, but says the company is going ahead and putting up better works and preparing to work the mine in a thorough and systematic manner.

NEW STAMP MILL.—A new stamp mill has been ordered for the Daisy Hill mine, Grass Valley, to crush tbe quartz and pay ore, together with the ore on the old dumps which, it is thought, will give good returns.

ASSESSMENTS.—The Live Oak Consolidated Mining Company has levied an assessment of ten cents per share, delinquent April 8th.

The Grizzly Ridge Mining Company has levied an assessment of three-fourths of a cent per share, delinquent May 10th.

The Odin Gold and Silver Mining Company has levied an assessmeut of four cents per share, delinquent April 26th.

Plumas.

RICH CHANNEL AT MCREA RIDGE.—*National-Bulletin:* A strike has been made at McRea Ridge hy the syndicate which has the Franklin and Beckwith Consolidated gravel mines bonded. During the past summer and winter the company has had a force of men at work running a tunnel to open up an ancient river channel known to exist in tbe ridge. Tbe miners, in driving this tunnel into the mountain, cut into the channel and found a pay streak twenty-five feet wide. the gravel from it yielding from $20 to $200 to the carload.

These properties are five miles southwest of Johnsville, in both Plumas and Sierra counties, in a section which produces very coarse gold. A few years ago tbe owners of one of the mines worked a break from the channel by the hydraulic process. Although operating in a small way only, in about three years $50,000 was realized, most of it very heavy gold. One nugget weighed about $3400, and it was no uncommon thing to secure pieces valued at from $100 to $1000.

However, what at that time was thought to be a regular gravel channel was soon exhausted, and it became evident that the deposit had been pushed out of or had broken from an ancient channel in McRea Ridge. Abont a year and a half ago Mr. Doolittle, of Dutch Flat, visited the mine. Appreciating the favorable opportunity for opening up a rich drift mine of great extent in McRea Ridge, he interested with himself A. N. Towne and several other magnates, secured bonds on a few locations owned respectively by the Franklin and Beckwitb Consolidated companies (the purchase price agreed upon being $150,000) and last summer began running a tunnel, not, however, employing a large force nor prosecuting the work very energetically. If the rich strike proves what it is reported to be, the syndicate will have one of the best gravel mines in tbis part of California, and no doubt will operate it accordingly. The new railroad completed to Mohawk, and a big and prosperous mining camp at McRea Ridge, would make things boom in that part of the county.

Riverside.

GOLD GOING TO WASTE.—*Reflex:* The Briggs mine, near Winchester, yielded 3¼ pounds of gold from a nine-days' run. The machinery in use is crude and much gold goes to waste.

Sierra.

A CHAPTER OF ACCIDENTS.—One of tbe boxes of the dynamo in the hoisting works at the Empire mine, in Gold Valley, was burned out last Friday. On Saturday five wires of the armature were burned out, rendering the machine useless until repairs are made. Tbe same day the front part of the furnace at tbe chlorination works, for a distance of 12 feet, caved in, caused, it is supposed, from poor brick. It will take two or three weeks to make tbe repairs, and in the meantime the mine will be closed down.

Trinity.

CANYON CREEK.—Ralston & Spencer, on Fisher gulch, bave cleaned out the tunnel on the Fisher gulch mine and are driving ahead.

About three-quarters of a mile from the Fisber gulch mine G. L. Bailey is running a tunnel to tap the ledge. The rock goes $20 to $25 a ton.

The lessees of the Cbloride mine have resumed work for the summer. The mill wbich was crushed by the snow last winter was but little damaged.

NEVADA.

WORK AT AUSTIN.—Elko *Independent:* The Austin Mining Company has a large supply of concentrating ore on hand, and E. W. Brownell will start the concentrator about the first of April. The company paid off on the 15th, their being between fifty and sixty employes on the payroll, and the concentrator will increase the uumber by fifteen or twenty.

THE COMSTOCK MINES.—At the Consolidated California & Virginia there bas been a considerable falling off in both the quantity and quality of the ore produced, hut it is to be hoped that this is only temporary. The yield the past week was fifty-two tons of the average value of $46.92 a ton. However, ore is still heing obtained in a number of places, and in one place on the 1650 level is a streak six feet in width that averages $60 a ton.

The Savage is yielding about 130 carloads of ore a week, the average assay of which is $28 a ton. Last week the company sent to the Carson Mint hullion to the value of $10,399.

Siuce repairing damages due to the late smash-up of machinery, the Crown Point Company have sent twenty-eight railroad carloads of ore to the Mexican mill, Carson river. This ore is gold-hearing quartz.

The Belcher, Hale & Norcross, Ophir, Justice, Chollar and Occidental are all yielding small amounts of good ore. At the Occidental ore is now heiug obtained on the 500 level that averages $40 a ton.

SIERRA NEVADA.—Have started an east crosscut from the southwest drift, started at a point 540 feet from the mouth of the Layton tunnel; advanced 39 feet during the week; face in porphyry, clay and quartz.

BULLION.—The west drift from the 820 level has been advanced during the week 14 feet; total length, 1433 feet; face in soft porphyry with a srrong flow of water.

ALPHA.—The east crosscut from the north lateral drift, 145 feet north of the main west drift, has heen extended 12 feet; total length, 24 feet; face in porphyry and quartz, from whicb there is a strong flow of water.

UNION SHAFT.—The joint west crosscut from the south lateral drift near the south line of the mine, 1520 feet west of the shaft, 900 level, has been advanced 15 feet during the week; total length, 600 feet; face in a formation of clay, quartz and porphyry.

Tbe joint east crosscut No. 3, from north lateral drift, 600 feet north of west drift, 1520 feet west of shaft, 500 level, has been advanced 20 feet: total length, 220 feet; face in porphyry and clay, witb small flow of water from it.

ALTA.—During the past week the north drift, 910 level, was advanced 18 feet; total length, 198 feet; quartz and porpbyry in the face. Arc casing above the 825 level in a streak of good ore 18 inches thick, the average assay value of which is about $40 per ton.

The official letter from the Occidental Con. mine states that the north drift from the west crosscut on the 500 level is now in 47 feet, and continues in ore averaging $41 per ton.

The official letter from the West Consolidated Virginia & California mine says that tbe west crosscut run from a point 320 feet north of the 1100-level station has been extended 12 feet, and is now in a total distance of 1474 feet; the face is in hard porphyry, carrying seams of quartz. The flow of hot water and temperature are the same as when last reported.

TWO ASSESSMENTS.—The North Truckee Drain Ditch Company of Reno has levied an assessment of $3 per share, delinquent April 19th. The Union Ditch Company of Reno has levied an assessment of 25 cents per share, delinquent April 18th.

ALASKA.

GOING TO THE YUKON.—The spring emigration to the Yukon gold fields has begun. On the 10th inst., nearly 200 Yukon miners had reached Dyea, 300 miles beyond Juneau, and tbe prospectors were hauling tbeir sleds upon slush ice up tbe great Dyea canyon toward the Yukon. More dogs bave been taken out from Juneau than ever before and the last steamer took up twenty-two from Puget Sound. They haul the prospectors' outfits over the ice and snow, greatly lightening the labor of the trip. William Liggett, who has beeu mining on the Yukon for six years, has returned to Juneau with glowing accounts of the rich finds made last season on Forty Mile, Sixty Mile and Miller creeks. Last season several dozen miners took gold worth $150,000 out of Miller Creek. So far the Discovery claim and seven others adjoining it on Miller Creek have yielded the greatest returns in gold nuggets, exceeding the yield of any other claims in the Yukon Valley. There was twelve feet of surface dirt upon the Discovery claim, which had to be sluiced off before pay dirt was struck on bedrock. The sluicing has to be done quickly, as the Yukon season lasts only sixty to ninety days.

ARIZONA.

THE NORTHERN PLACERS. — Yuma *Times:* Porter Laird is making big wages by dry wasbing, near Ebrenberg.

The Martinez company, east of Ehrenberg, are also doing well on tbeir ground.

Frost and his partner are located five miles east of Tyson's, and they have a shaft twenty feet deep. Every shovelful is rich.

Tbe Gray cement crusher, northeast of Ehrenberg, works satisfactorily aud prospecting for more material is now being done.

A steam arrastra is located a mile north of Tyson's, and is doing custom work on rich quartz.

Plomosa district is full of dry wasbers, and everybody seems to be making wages.

AT ROCKY PASS.—A stamp mill is to be built at the Rocky Pass mine, Cberry creek district, owned by Geo. Sines and T. H. B. Smitb. This mine is a shipping property, the ore averaging $40 to $60 gold per ton.

BRITISH COLUMBIA.

NEW DENVER DISTRICT.—*Miner:* At the No. 1 fifteen tons a day are being put tbrough the concentrator at Ainswortb, which is running day and night. The mine and the concentrator are employing about thirty men, most of whom are steady, hard-working Nova Scotians. Since January 1st 200 tons of ore have been shipped from this mine to the smelter at Pilot bay.

The Little Pbil and the Black Diamond claims are making a good show. Seven men are working on the joint properties, which have sent out 255 tons to the smelter at Great Falls, Mont., since the heginning of the year. The smelter gave the high return of 700 ounces to the ton for some picked ore.

Work has been commenced on the Rand and on the Indicator, a northwest extension of the No. 1. In June the "Mile Point" will he up again. Ore from this latter property bas assayed as high as 400 ounces to the ton, with ten per cent of lead.

Thirty-five men are at work on the Blue Bell, across the lake, under H. Stevenson, and they are sending down 150 tons a day to the smelter at Pilot bay.

A STEP UPWARDS.—The starting of the smelter at Pilot Bay marks an era in the history of the Kootenay mining district. The district generally is one of the roughest in North America, and until railways were constructed and steamboats took advantage of its magnificent waterways it was practically inaccessible. Three railways now tap it—the C. P. R. to the uorth, the Great Northern and the Nelson and Spokane line to the south. For years the project hung fire. To-day its furnace is producing ingots of silver-lead.

COLORADO.

CRIPPLE CREEK.

A LARGE OPERATOR.—Besides the great Independence mine, Mr. Stratton is now working the Portland No. 2, the Logan, the Eagles and the Yankee Girl, and the Caledonia is heing worked under lease. He is buying new properties whenever he finds an investment to his liking, and has been about the only heavy cash investor in the Cripple Creek district for a year past.

CONTROL OF THE VICTOR.—*Republican:* Report has it tbat the Victor mine at Cripple Creek is wanted by a French syndicate and that G. P. Walsh bas just completed his examination on which the decision of tbe foreign investors will be based. The Frenchmen bought 45,000 sbares of the stock at $3.50 and have had dividends which satisfy them that Victor stock at par is better than South African investments, with which they are more familiar, so they are now dealing for a control of the company, and it is claimed have an understanding with D. H. Moffat and Eben Smith for the purchase of their holdings at about $5, and that only the report of the expert is needed to complete the sale. The Victor is incorporated for $1,000,000, with shares $5 each.

There is now a perfect furore for South African gold stocks in Paris, and the sale of the Victor is likely to open the way for many other investiments of French capital in the Cripple Creek district. Professor Walsh has examiued the Buena Vista mine and it may he taken up by the same parties.

PIKE'S PEAK MINE.—Cripple Creek *Times:* The last two carloads of ore from the Osborne lease on the Pike's Peak mine, returned $13,132 and a sack of twenty-nine pounds gave returns of $305.

TELLURIDE.

RENEWAL OF WORK.—*Republican:* Arrangements have been made for the renewal of active work on tbe Keystone placers and tbat with the opening of the season the big hydraulic giant will agaiu be started to washing down its rich banks of auriferous gravel. The presence of gold in those banks to as high a value as $2.50 per yard has been demonstrated in tbe past.

RICO.

RICO'S SHIPMENTS.—*News:* The following is the number of carloads of ore sbipped from the various mines of Rico since January 1, 1895: Blackhawk, 71; Rico-Aspen, 82; Enterprise, 48; Princeton, 23; Swansea, 1; Munn Bros. (sampler), 3; Sberidan, 24; Pigeon, 4; Iron Clad, 1; South Park, 2; iron Mine, 1; total, 260.

IDAHO.

AT CHLORIDE CAMP.—The Webber Mining and Milling Company's plant started up about a week ago with fifteen men, since which time they have been turning out twenty-five tons per day. Shipping has already commenced. The ore is free milling, and, while not extra rich, is easily handled, and there is enough in sight to run the mill a year.

GENERAL ACTIVITY.—An unusual amount of mining activity is going on in the Gibbonsville and Shoup districts. The building of a forty-stamp mill by the American Development and Mining Company and other developments of the Barclay property will give this part of Idaho a substantial and lasting boom.

News from the Willow creek mining district is encouraging. Prout & Richardson have a stamp mill nearly ready for operation, and much development work will be done there this season. Posten & Critzer, of Caldwell, are running a sixty-foot tunnel on the Hoosier ledge and report excellent indications.

MONTANA.

ASBESTOS.—A large deposit of asbestos was recently discovered twelve miles northwest of Dillon, Mont., and can be traced for a distance of 2500 feet.

OREGON.

BAKER.

A gold nugget weigbing a fraction over $60 was picked up in tbe gulch below tbe Virtue mine, one day recently, by Mr. Casebeer, who intends placer mining on tbis claim in a few days.

STRUCK A POCKET.—*Oregonian:* Frederick Holton came here from Baker county this morning, carrying with him a valise filled with gold nuggets, the weigbt of wbich made him stagger. Some of the nuggets weigh $3000, and the whole treasure was dug out of a pocket by himself and his partner, Henry Sanderson, witbin the past four days. Holton and Sanderson had been prospecting in the hills of Baker county almost a year witbout making "grub" money, and a week ago they were about abandoning the field and returning to California. On Tuesday last they saw some float rock close to their temporary camp, and following it up they struck a pocket, from which, Holton says, they have already taken $40,000. He believes that there is $500,000 or more of gold in that depository, which can he taken out with no cost beyond their personal labor. [The above sounds well, but needs verification.—ED.]

BOHEMIA DISTRICT.

TO BE SOLD.—The Annie Consolidated Mining Company's property in the Bohemia district is advertised in the Roseburg papers to he sold at sheriff's sale on Thursday, April 4, 1895, on a judgment in favor of James Pitcher, for $614 39, and $61 25 costs and dishursements.

UTAH.

TRANSFER OF THE CAROLINE.—*Tribune:* The formal transfer of the Caroline mine to the Bullion-Beck Company was effected yesterday at a straight-away price of $130,000. That amount was $15,000 less than the price quoted when Mr. Badlam so vigorously protested against the purchase.

Mr. Badlam came all the way from San Francisco to protest against the proposed purchase of the Caroline by the Bullion-Beck Company, claimiug that tbe latter already owned all that was valuable of tbe Caroline. Mr. Badlam also served a written notice upon each of the directors of the Bullion-Beck Company, in which he stated that he would hold them personally respon-

sible if they concurred in the purchase and permitted it to go through.

As previously stated, the Caroline is to be under the active management of Captain Hank Smith.

The Caroline is showing up splendidly, although it has only been worked in a comparatively small way recently, and big changes are expected in the immediate future.

THE SILVER KING.- Speaking of the new find in the Silver King mine, the Park City *Record* says that new bodies of ore are uncovered so rapidly, and show up so strong and rich, that even the oldest men underground become bewildered and wonder if the end will never come. Since the power drills have been in use, a number of prospecting drifts have been run in all directions and ore found everywhere, but the cap sheaf was placed on the shock yesterday, when the shaft, which is being sunk to the 1100 level, dropped into a fine body of rich ore.

WASHINGTON.

SLATE CREEK DISTRICT.—The steamer City of Ellensburg is chartered by Messrs. Clark & Co., who are shipping several carloads of mining machinery into the Slate creek mining country. About fifty men will take passage on the boat for the mines, thirty-eight being practical miners from the Sound who are hired by Messrs. Clark & Co. to work in the mines, the rest being miners and business men looking for locations. The present indications point to a prosperous season for river traffic on the Columbia between Wenatchee and the mines.

Miners from the Squaw creek country confirm the report of the rich strike two miles from Methow City on the Doerr ranch.

Technical Society of the Pacific Coast.

The next regular meeting will be held on Friday, April 5, 1895, in the rooms of the Society in the Academy of Sciences' building, 819 Market street.

On this occasion Mr. J. D. Isaacs will present a paper entitled "Stopping a Troublesome Slide at a Summit Tunnel," which discusses the successful engineering results of overcoming physical difficulties. Members are requested to attend and invite any friend interested in the subject.

It is hereby announced that this Society has become a member of the Association of Engineering Societies, and that its professional papers will hereafter appear in the journal of the Association published in Philadelphia. All members are entitled to receive this journal without additional charge to them, the subscription beginning with the March number, which will appear in due time.

In this connection it is earnestly requested that all members of the Technical Society who have not placed themselves in good standing to do so at the earliest opportunity, so that the Society may not lack the funds to meet the obligations to the Association.

By order of the President.

OTTO VON GELDERN, Sec'y.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 19, 1895.

536,169.—WAVE MOTOR—C. L. Caldwell, Los Angeles, Cal.

536,069.—WAGON TONGUE SUPPORT—J. F. Dehm, San Diego, Cal.

535,955.—BURIAL CASE—T. C. Nativel, Los Angeles, Cal.

535,956.—WINDMILL—C. A. Norcross, Reno, Nev.

536,157.—NECKTIE FRAME—G. W. Ritz, S. F.

535,984.—GAS ENGINE—H. Swain, S. F.

535,930.—WINDOW SCREEN—W. Thompson, Santa Cruz, Cal.

536,111.—STRINGING PIANOS—C. S. Neber, San Jose, Cal.

535,970.—ADVERTISING DEVICE—C. L. Whipple, Los Angeles, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

THE Altham motor, about which so much has been said and sung, is being exhibited in Boston and is regarded as a success. It is a new type of turbine wheel operated by a small jet of steam or a hydrocarbon fuel which is fed automatically into a generator, where its combustion produces a gas under heavy pressure, which in turn is fed to the turbine in the same way that steam is now injected. The motor now on exhibit is cylindrical in form, about 18 inches in length by about 12 inches in diameter. It is coupled directly to the shaft of the armature of an old type of dynamo, and with about 14 horse power of steam energy it generated quite easily current for 100 lamps of 16 candle power capacity.

THE battle of Waterloo was fought 80 years ago. There are now living 23 known survivors of that great conflict. Of these 14 live in England, six in France and three in this country. The battle of Waterloo was fought 50 years before the close of our civil war. Within 50 years, therefore, it is probable that the number of Union veterans or those who fought for the Confederacy will be reduced to very small proportions. The average of human life is increasing, and though the hardships of their war experience have shortened many lives, it seems probable that as many, if not more, will survive of those who took part in our civil war as there are now survivors of the battle of Waterloo.

THE air-tight compartment theory of building ships was copied from a provision of nature shown in the case of the nautilus. The shell of this animal has forty or fifty compartments, into which air or water may be admitted to allow the occupant to sink or float as he pleases.

ONE of the most peculiar coals found in the United States is the lignite of the Dakotas. It looks like slabs of wood blackened, and the knots and burls in the timber are plainly to be seen.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents Inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliable.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the globe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

The Explorers' and Assayers' Companion.

A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."

By J. S. PHILLIPS, M. E.

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.

The work is divided into four parts: Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulas as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Price $5.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

The I. B. HAMMOND CO.

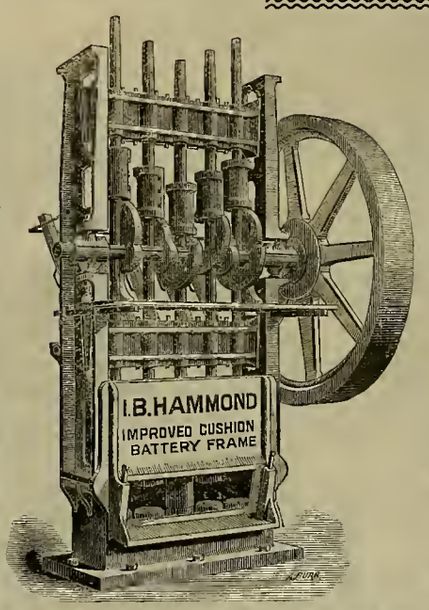
69 First Street, PORTLAND, OR.

MANUFACTURERS OF

Stamp Mills, Ore Feeders

DETACHABLE BUCKET WIRE-ROPE TRAMWAYS,

Roller Grinding Pans, Desulphurizing Furnaces, Etc.



Improved Self-Contained Cushion-Frame Five-Stamp Mill.

The Improved, Iron-Frame, Self-Contained, Cushion-Frame, Five-Stamp Mill Saves Bills for Heavy Timbers, Millwright and Mechanics' Labor, and a Large Amount of Space. The Term "Self-Contained" Means a Great Deal to the Mine Owner, and Can Be Readily Recognized and Appreciated in Making an Estimate For an Ordinary Five-Stamp Plant, When the Comparative Cost Is Considered Over a Wood-Frame Mill.

FIRST: There is Saved by the Use of This Mill a Large Bill for Heavy Timbers, In Many Instances Obtained at Great Expense and Loss Of Time.

SECOND: The Saving in Mill-Wright and Mechanics' Labor in Framing and Erecting.

THIRD: The Large Amount of Space Saved.

THE AMERICAN MINING & MILLING MACHINERY CO.,

121 Euclid Ave., CLEVELAND, O. 280 Caxton Blk., CHICAGO, ILL.

SPECIALTIES:

AM. CRUSHER AND AM. BALL PULVERIZER.

The simplest, cheapest and best machines in the market. Pulverize wet or dry to any degree of fineness. Make little or no slimes in wet nor dust in dry work. Four sizes, capacity from 2 to 60 tons per day.

SEND FOR CATALOGUE. Cable Address, American.

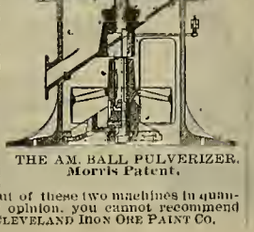
First Prize and Gold Medal Awarded by World's Fair, 1893.

Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O., Jan. 25, 1894.

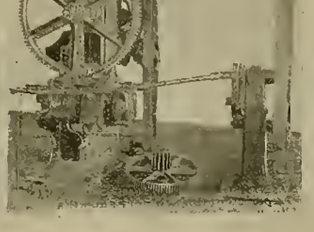
The American Mining & Milling Machinery Co., Cleveland, O.:

GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out both stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4⅞ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows less; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with less than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,

CLEVELAND IRON ORE PAINT CO.



THE AM. BALL PULVERIZER. Morris Patent.



GEAR CUTTING

A SPECIALTY.

Fine Work at Bedrock Rates.

SPUR, BEVEL, and WORM GEARS of any pitch or size up to 50 Inches.

Uses of Sawdust.

One of the methods whereby profit has been made from sawdust is the manufacture from it of oxalic acid, which is a simple process, producing a material in wide commercial demand in the art of dyeing and other chemical arts. As intimated, the process is not only simple, but the outfit for conducting it does not involve a large investment. The principles involved are not complicated, and the process can be carried out by cheap labor under the superintendence of a fairly intelligent director.

Oxalic acid is frequently met with in the vegetable kingdom, especially in combination with gases which destroy its poisonous character. Oxalate of lime is found in considerable quantity in the rhubarb plant. Oxalate of potash is found in the sorrel and oxalate of soda in salicornia and sal soda. Formerly the acid was obtained from the sorrel, Oxalis acetosella, but more recently from sugar by the action of nitric acid upon it. The nitric acid and sugar are boiled for some time, then evaporated to dryness, and the oxalic acid formed is purified by crystallization from water. A much cheaper material than sugar is sawdust. In this case an alkali must be employed instead of an acid, as well as at a higher temperature. The operation is conducted in an iron vessel of suitable size and shape, and either caustic soda or potash is employed, the yield being greater with the latter.

Some experiments made go to prove that a mixture of forty parts of caustic potash to sixty parts of caustic soda will produce as large a yield as when potash alone is used, provided the operation is performed in shallow vessels with thin layers of the material, avoiding, as far as possible, the fusion of the mass. Soft woods, such as pine and fir, produce larger quantities of oxalic acid than hard wood like oak. The proportion of the wood to alkali should not exceed 75 to 100, and the temperature should be about 480° F.

Natural Bridge in Oregon.

One of the chief of the west coast natural curiosities is the "Titan's Bridge," situated in Douglas county, Oregon, and about eighteen miles from Oakland. It is not on such a grand scale as the famous "Natural Bridge" of Virginia, but will, when its whereabouts become generally known, rank high among American oddities of nature. This Oregon natural bridge was discovered only a few years ago by a Californian of the name of Magee. The canyon spanned by its arch is 91½ feet wide at the base between side walls, and the arch itself only lacks 4½ feet of being an even 100 above the little stream that runs beneath. The rock stratum which spans the canyon and forms the bridge is 30 feet in thickness, exclusive of 3 or 4 feet of earth, which supports a few straggling trees. It has already become a great resort for Oregonian outers, and a large hotel on a plateau near the western approach of the bridge is among the near future probabilities.

Artificial Whalebone.

According to *Le Genie Civil* the Munck process for the manufacture of artificial whalebone consists in first treating a raw hide with sulphide of sodium and then removing the hair; following this, the hide is immersed for a period of twenty-four to thirty-six hours in a weak solution of double sulphate of potassa and is then stretched upon a frame or table, in order that it may not contract upon drying. The desiccation is allowed to proceed slowly in broad daylight, and the hide is then exposed to a temperature of from fifty to sixty degrees. The influence of the light, combined with the action of the double sulphate of potassa absorbed by the skin, renders the gelatine insoluble in water and prevents putrefaction, the moisture, moreover, being completely expelled.

Thus prepared, the skin is submitted to a strong pressure, which gives to it almost the hardness and elasticity which characterize the genuine whalebone, with the advantage that before or after the process of desiccation any color desired may be imparted to it by means of a dye bath. The material can be rendered still further resistent to moisture by simply coating it with rubber, varnish, lac, or other substance of the kind.

100,000,000 Acres.

The United States Surveyor-General for California estimates the area of the State of California to be 100,395,000 acres, as follows:

	Acres.
Agricultural and mineral lands surveyed to June 30, 1892	61,887,392
Agricultural and mineral lands unsurveyed	26,211,501
Private grants patented	8,383,375
Private grants not settled	341,650
Indian military reservations	318,631
Lakes, islands, bays and navigable rivers	1,531,700
Swamp and overflowed lands surveyed	1,635,227
Swamp and overflowed lands unsurveyed	85,524
Total	100,395,000

Stamp Cam.

Witwatersrand Gold Product.

A report by Hamilton Smith upon Witwatersrand gold fields was published about two years ago, based upon an examination of the Rand in 1892. He has lately revisited the Transvaal, remaining there from August to December, 1894. In the former report his belief was stated that in a few years the gold product from the Rand would increase to a value of over £10,000,000 per annum, and that a total yield of £325,000,000 in gold could be reasonably expected from that district.

Since 1892, work has been carried on more vigorously than ever before in about sixty mines owning claims at and near the surface outcrop of the main reef series. Many vertical bore-holes have been put down by diamond drills, one having reached the depth of nearly 2500 feet. Mr. Smith believes that, at a horizontal distance of three miles from their outcrop, the reefs of the main series are probably 10,000 feet, or about two miles, beneath the surface. At a distance of two miles, their depth, as a rule, will be not quite one and one-half miles.

The vertical depth to which these mines can be worked with profit will chiefly depend upon the value of the ore, the amount of capital required for plant and development, the quantity of water to be pumped and the temperature of the ground. With the abundant supply of coal in the Rand the cost of hoisting the ore from great depths will not be a very important item. None of the mines on the Rand have thus far encountered large inflows of water. In regard to the heat, Mr. Smith was able to make some careful determinations of the temperature in the deep bore-hole before spoken of. These show a temperature of 67.2 Fahr. at a depth of 200 feet, increasing in a regular manner to 95.3° at a depth of 2494 feet. This indicates a temperature of about 100° at a depth of 3000 feet. At the depth of 3500 feet the high temperature will probably cause a serious addition to the mining costs. Mr. Smith thinks that, with most of the mines, a vertical working depth of but little over 3000 feet can be assumed as the limit with which they can be operated at a profit, while with richer or thicker ore—such as is now found in a few of the outcrop mines—a limit of something over 3500 feet in depth seems reasonable. Should, however, the price of skilled labor and the cost of supplies decline in time to a European level, still deeper limits would be possible.

As to the continuance of the gold with increased depths, there is no sign whatever up to the present time of any change in the grade of the ore. Present indications show that the average values of the reefs remain unchanged to a vertical depth of 1000 feet—say 1750 feet upon their dip.

Mr. Smith reports that in 1894 the value of the Rand gold bullion was £7,000,000, and this without any increase from the new deep-level mines. These latter will become fairly productive in 1897, so for that year a product of fully £10,000,000 can be fairly expected. "Judging from present appearances, the maximum product of the Rand will be reached about the end of this century, when it will probably exceed £12,500,000 per annum." The Rand for 1894, with its product of $35,000,000, stands third in the world, the United States being first with its output of over $45,000,000, and Australasia being probably second with a product of about $40,000,000. In 1849 the world's product of gold was about $30,000,000, which increased to something over $150,000,000 in 1853, owing to the discovery and working of the rich placers of California and Australia. From 1853 the yield steadily declined until, in 1883, it had fallen to less than $100,000,000. Since 1887 the yield has advanced by leaps and bounds until for 1894 the product has most probably amounted to fully 8,600,000 ounces of fine gold, worth over $182,000,000—an output certainly much greater than that for any previous year in the history of the world. It has been generally accepted that one of the principal causes of the rise in the price of standard articles from 1849 to 1860 was due to the influx of gold from California and Australia. Will the same rise in values, measured by the ounce of gold, take place in the coming five years? This is a question of vast importance to all of us—from the richest capitalist to the poorest laborer.

From the Rand mines, since their commencement in 1887 up to December 31, 1894, Mr. Smith estimates that 10,110,000 tons of ore (2000 pounds each) have been extracted, yielding 6,544,584 ounces of gold bullion, worth about 69s per ounce, and thus having a gross value of about £22,600,000. The dividends paid by the producing mines during the same period amount to £4,484,541; but of this sum nearly £200,000 was unquestionably not fair mining profit, so that £4,300,000 can be assumed as having been the net return, or nineteen per cent of the output. For the year 1894 there was milled 2,827,365 tons, coming from fifty producing mines, yielding 2,024,162 ounces of bullion, worth about £6,980,000, and the dividends declared by them for the year amount to £1,406,266, being twenty per cent of the output. On the other hand, several of these mines were operated at an actual loss in 1894. From 1887 to 1894, inclusive, the profits made in actually working the mines of the district have been more than the losses, although in the years 1887-90 large sums were expended in developing mines, many of which thus far appear to be worthless.

DEWEY & CO., 220 Market St. SAN FRANCISCO,
PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, March 28, 1895.

The five States of Montana, Colorado, Utah, Idaho and Nevada are directly concerned, and the rest of the Union indirectly concerned, in the gratifying advance of silver. The MINING AND SCIENTIFIC PRESS rejoices, not at the verification of its predictions, but because it is a general vindication of what all friends of silver have claimed—viz., that the natural trend of events and the public requirement would overcome the manipulations of those who trade upon the necessities of the nations and the weakness of legislators. In this regard, it is noticeable how little notice has been made of the resumption of free coinage in India by Great Britain. For the past sixty days, as receutly noted in these columns, free coinage is now going on in Bombay, where England is coining "the British dollar," containing 416 grains of silver. England finds it profitable to buy silver even at 64c, to-day's quotations, as 416 grains in a dollar means just twice 64c for silver hullion. English papers say this is done "for the relief of the banks." Whatever the motive, the fact remains the same. The "seigniorage" at the Bombay mint is one per cent.

A suggestion herein made some time ago—that the market for silver could and should be made and the rate set here, and not in London, meets affirmative echo in many quarters. The scheme is feasible, and some day to that it will come.

Says Dan De Quille: "The 'kept' papers of the gang in the East who are working the gold cinch on the producers of the land, are always talking about the danger of Europe unloading silver upon this country. The fact is that England and other countries across the water have use for all the silver they possess and all they can get from this country. Every week we send across the sea to the Old World from $400,000 to half a million in silver. If there is no silver needed in the other countries of the world no such amounts would he taken. In the last eight months over $23,800,000 in silver has heen sent from New York to London. Of course, Johnny Bull finds a place for this silver and is making a hig thing out of it."

"Instead of sending their silver hullion to London via New York our people should send it to China and Japan via San Francisco and use it in the purchase of tea, silks and other goods of the Orient, for which there would he ready sale here aud in Europe at good prices in gold. It would not be long after the shipments of silver were thus turned away from New York and Londou before the manipulators, here and across the water, who have heen putting their own price on our silver (and thus putting their own price on all the products of our farms and planters) for the past twenty years, would hegin to haul in their horns. It is an experiment that should he made, ard just now is a good time in which to make it. A syndicate could easily he formed to run the whole business, and it would soon be the strongest in the world."

Mining Share Market.

SAN FRANCISCO, March 28, 1895.

Throughout the week there has been little husiness and low prices for the little done. The advance in silver or the improved appearance in the Comstocks have little to do with the street. Money, nerve and a leader are needed, and the lack of all three makes things spiritless. The chipper bears about the same relation to stock business that the check guerilla does to the faro bauk. Occidental showed a little life and Bodie was firmer. Con. Cal. advanced and to-day the market livened up a little.

The following illustrates the changes of the week:

RUPTURE!

It has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

DELINQUENT SALE NOTICE.

INYO MARBLE COMPANY OF CALIFORNIA. Location of principal place of business, San Francisco, California. Location of works, Inyo, Inyo County, California.

And in accordance with law, and an order of the Board of Directors, made on the Eighteenth day of February, 1895, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the salesroom of S. P. Middleton & Co., No. 30 Montgomery Street, San Francisco, California, on WEDNESDAY, the Seventeenth day of April, 1895, at the hour of Two o'clock P. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

GEO. R. SPINNEY, Secretary.

Office—310 Pine Street, Room No. 28, San Francisco, California.

WANTED.

A competent man to canvass for advertisements for *The Colliery Engineer and Metal Miner* on the Pacific slope, with headquarters in San Francisco. Address with references,

THE COLLIERY ENGINEER CO.,
Scranton, Pa.

Coast Industrial Notes.

W. A. Hewitt, 11 First St., represents the Western Forge Co., of St. Louis.

Wellington coal importers have combined, and put the price up 50 cents per ton.

E. A. Rix has removed his machinery business to 11-13 First St., San Francisco.

—Eureka Mill owners can manufacture redwood lumber cheap enough to compete with Oregon pine in price.

—Parties from Puy de Dome, France, will start a factory in California for the preparation of crystallized fruits.

—The Beaver Hill Coal Co., with a $500,000 capital stock, has been organized to open new coal mines at Coos Bay, Or.

—There are 2200 carpenters in this city. Of that number, 1500 are employed at wages ranging from $1.75 to $2.25 per day.

—The Watsonville sugar factory, near Santa Cruz, has closed a long season's work. The total amount of beets handled during the season is estimated at 142,000 tons.

The Sacramento *Record-Union* has ordered five type-setting machines, which will do the work of thirty-five compositors. The machines will arrive about July 1st.

A lease has been taken of 2500 acres at Whittier, Cal., by Pennsylvania and New York operators Pickering Land and Water Company—and boring for oil will commence.

—The Hobart & Marlette estate owns a tract of timber land near Truckee, and now intend to work the timber into lumber. A mill and yards will be established at Boca or Truckee.

—The Pacific Coast Steamship Company has decided to put on extra steamers of light draught to call at the ports of Mazutlan, Altata, La Paz and Guaymas, in the Gulf of California.

—The Redondo iron mines, Redondo island, B. C., and the Glen iron mines, near Kamloops, have been bonded by an American firm, who are negotiating to establish iron works near Seattle.

—Shipments of wine to this city to fill the sale of 6,000,000 gallons to the California Winemakers' Corporation, have begun from Santa Clara county, which will furnish about 2,000,000 gallons, at 12½ cents a gallon.

—Professor Sanders, of Fresno county, gives it as his opinion that tea can be grown in several parts of California, but, by personal experience, says that the harvesting of it requires two days' work to produce one pound, worth fifty cents.

—San Francisco people are paying ten cents per pound extra for California prunes with a French label on the box. The *Democrat* thinks it is a wonder some of our miners never thought to put a European label on their gold; they might sell it at a big advance to the same people.

—The Washington bureau of equipment states that tests made of the Blue canyon, Washington, coal show that it has equal qualities to that of any other Pacific Coast coal yet tested—showed fixed carbon of sixty per cent. The results of the tests made by the Mohican corroborate the report thus far.

It is said that a syndicate of wealthy men are arranging to send an agent to China, believing that as soon as peace shall have been concluded between China and Japan the celestial empire will become the scene of wonderful development in railways, street car lines, factories and other means of internal improvement, and there will be opportunities for franchises or concessions which may lead to the making of large fortunes.

—Among recent pipe shipments is one of 1000 feet, 28 inch, three-sixteenths by Francis Smith & Co., to Honolulu, accompanied with a ninety-foot span beam bridge to carry it.

—The Keystone Foundry of Los Angeles has secured an outfit of iron-working tools from the Parke & Lacy Co., of this city. An Ingersoll-Sargeant compressor with drill has also been sent to the Osborn Hill Gold M. Co.

—A gasoline launch is being built to run between Sacramento and Red Bluff by George W. Kneass, the boat-builder. The launch will be forty-eight feet long, ten feet beam, and five feet deep. She will have accommodations for twenty passengers, and will be propelled by a gasoline engine of twenty-horse power.

The ruling in the Short Line case recently at Portland, Or., is a victory for the Union Pacific. Circuit Judge Gilbert and District Judge Bellinger decline to take the case out of the hands of District Judge Ryner of Wyoming, who originally appointed the Union Pacific receivers to be receivers also for the Oregon Short Line.

Flagstaff, Arizona, men, have organized the Durango, Flagstaff and San Diego Railroad Company to build a railroad from Durango, Col., to San Diego, a distance of 760 miles, to cost $6,000,000. The incorporators are D. M. Riordan, D. Babbitt, J. W. Francis, W. Hamilton and J. R. Kirkpatrick, who have subscribed $3,000,000.

—The California State Board of Trade has decided not to send an exhibit to Mexico, but to send one to the Atlanta Exposition. The following directors were elected to serve for a year: J. S. Emery, B. M. Lelong, Hon. L. W. Buck, J. Morrisey, J. S. Stabler, W. H. Mills, N. P. Chipman, J. P. Irish, C. M. Wooster, L. C. McAfee, M. L. McDonald.

—The Board of Directors of the Manufacturers' Association have elected the following officers: President, H. T. Scott; Vice-Presidents, Louis Saroni; W. F. Bowers and J. M. Davies; Treasurer, Andrea Sbarboro; secretary, Lewis R Mead; Executive Committee—R. S. Moore, James Sproule, Julian Sontagg, M. McGlynn and Louis Saroni.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Send for it on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

HEALD'S

Business College,

24 Post Street, - San Francisco.

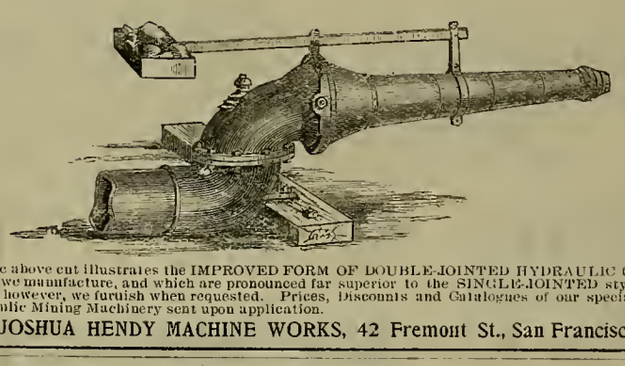
FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.

A Department of Electrical Engineering

Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.

FRANCIS SMITH & CO.,

—MANUFACTURERS OF—

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

130 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one-third the cost in wear of any other crusher on the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

The Pelton Water Wheel Company, General Western Agents

121 Main Street, San Francisco, Cal.

NOTICE TO GOLD MINERS!

SILVER-PLATED AMALGAMATED PLATES

For Saving Gold

IN QUARTZ, GRAVEL OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER.

AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates replated, bought, or gold separated. THOUSANDS OF ORDERS FILLED.

C. J. Clark, M. E., Gen'l, Supt. Dec. 12. 1891.

MESSRS. ADAMS & CARTER, San Francisco. Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailing from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.

Arrastra—"The Poor Man's Mill."

Stamp mills and roller quartz mills, which were described and commented on at considerable length in last week's issue, have not wholly taken the place of a means of crushing quartz, crude but effective, still in use in some parts of this State. Reference is made to the arrastra—"the poor man's mill," which, as well as the Chilean mill, a development from it, are not extinct, as the accompanying illustrations show, being taken from direct photographs of arrastras now in operation in Kern county. As noted, one is worked by horse power, one by water power, and one by steam power, which in itself is considerable advance over the burro power of Old Mexico, and whilom of sections farther north.

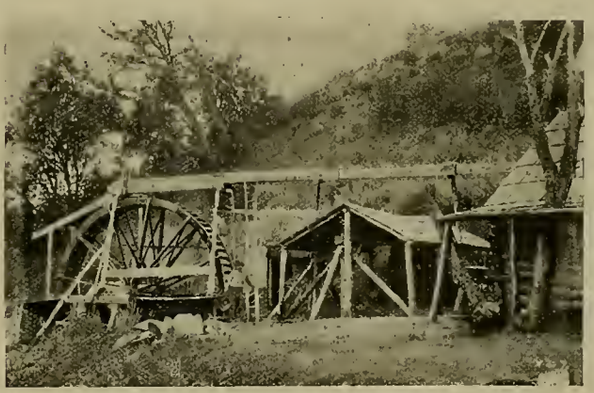
There isn't much said about arrastras, and where there is a big mine, or a mine not so big, but some capital, there needn't be, for an arrastra seems as slow and stupid as the donkey that drives it in its native place; but, primitive as the arrastra may seem and weakly productive in comparison to roller or stamp mill, it has an honorable though humble record, and has ground out many a dollar's worth of bullion in its simple old way. With all its rudeness, it deserves a word of praise. Unlike some mills, it never beats the company; the battery assays and car assays agree; the ore owners know that what goes in comes out, and there is no addition, division or silence. And with free gold it will hold its own with many a costly mill. It costs very little to set up; the running expenses are light; it rarely breaks down, and when it does can be cheaply and quickly fixed up; it needs little housing, watching or insurance; it can be built by the owner, who can be his own engineer, millman, foreman, amalgamator, feeder and boss, and the one man who combines all these positions can break the rock and keep the burro or the mule or the horse going all at once. Nothing blows up, and unless the mule gives out there isn't much prospect of loss; the amalgamation is usually satisfactory, and while there isn't much science nor style about the outfit there's considerable common sense and often lots of profit. It is not recommended as a superior article; it bears the same relation to better, faster, finer appliances for the same purposes that a country blacksmith shop does to the Union Iron Works, but "it beats nothing all to pieces," and in many an isolated mine would pay better to work ore than to have the owner sitting around "waiting for capital" to develop his claim, and thus work out his own salvation.

The arrastra is slow but sure. It is built in a primitive way, solidly and securely, its two greatest drawbacks being its limited capacity and liability to waste.

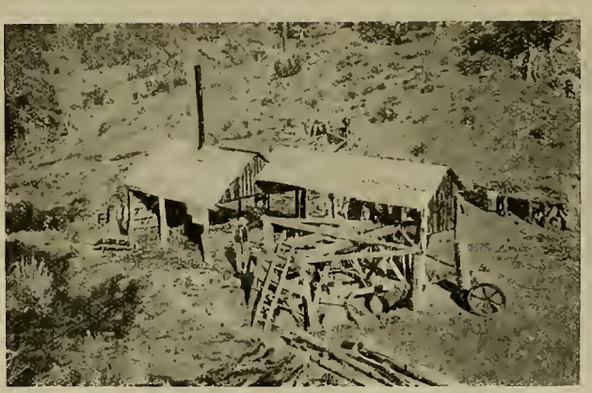
Judge Sumners' Kernville arrastras are in a granite country, much of it with feldspathic veins or dikes crossing, the arrastras occupying the site of a twenty-stamp mill built thirty years ago, but long since entirely removed, with the exception of the battery blocks.

The arrastras at Smartsville and Mooney Flat districts, Nevada Co., are twelve feet across and three feet deep. The bottoms are paved with hard, rough-dressed rock, laid evenly in cement and sixteen inches in depth. The center post is fourteen inches square, eighteen inches high, the post having four arms, to each of which is attached a heavy drag.

HORSE POWER ARRASTRA, KERN COUNTY.



WATER POWER ARRASTRA, KERN COUNTY.



STEAM POWER ARRASTRA, KERN COUNTY.

The drags are heavy diabase blocks clamped to the arms, so fixed as to cover all parts of the pit as they go round. Each block weighs from 700 to 1200 pounds. About seven tons of gravel are run in from a car or a chute, water being added to keep it from caking, and the arrastra run very slowly till the mass is of a "thin mush" consistency, when a speed of about fourteen revolutions a minute is attained (this arrastra ran by steam power). After an hour of this the gate is opened and the charge run into the 200-foot sluice containing the riffles, the sluice being cleaned up weekly. The result for cement or soft top gravel gave satisfaction, the cost of milling being eight cents per ton.

In the regular old-fashioned Mexican arrastra, run by a burro, the bed is built of paving stones laid on a puddled clay five inches deep, set closely, the joints tamped with clay; in the center a large-sized stone as a step for the "peon" or pivot, made of two pieces of timber 4x8 clamped together. A hole is bored in the bottom and a piece of round two-inch iron, worked off to a rounded point at the lower end, inserted. Through the peon at right angles are passed two pieces four-inch square, one extending horizontally seven feet six inches, to which the burro is hitched; to the other is attached the mullers or grinders. These are of rough stone, prismoidal in shape, thirty-six inches long and about fifteen inches wide, so dressed as to throw the center of gravity well toward the base. At the upper end of each stone's front face two six-inch plug holes are drilled, in which are fitted plugs of dry sugar pine, which, when wet, swell and are immovable. The outside edge of one stone works a little in advance of the inside edge, thus throwing the charge toward the center. Of course, in setting the other stone, this arrangement is reversed.

The upper end of the peon is fixed in a four-inch pinion, which works in a bearing collar made of wood 2x8 inches; the collar is mortised near each end 1x3 inches, corresponding holes being made in the other timber and the two secured by a wooden link and pins. With such an arrastra a 600-pound charge is usual and the patient "mauana" worker gets enough to satisfy his needs, his chief lookout being to see that no grease gets near his machine.

The Chilean mill is sometimes associated with the idea of the arrastra, from which it may be considered to have been developed. It is to all intents and purposes a millstone set on edge and so arranged that it will revolve in a circular track, the axle upon which it revolves being pivoted at one end, the mule hitched to the other. As an expedient in out-of-the-way places the Chilean mill and the arrastra both serve a purpose, the Chilean mill reducing the assorted spalled ore to pea size, thence to the arrastra, where about one-half the charge is first placed and thoroughly moistened as the peon revolves, about two and one-half ounces of quicksilver being added as the grinding progresses, and the remainder of the charge is put in. From twelve to sixty hours is the limit for grinding, which depends on the nature of the ore and coarseness or fineness of the gold, amalgamation in the case of coarse gold being sometimes reached in twelve hours and in the case of fine gold requiring even more than sixty hours. The accompanying apparatus for settling, retorting, etc., is necessarily rude but in most cases effective. In this brief notice of a primitive gold producer no attempt is made to give the detail of setting up or working, the subject being treated in outline in the most general way.

CORRESPONDENCE.—The Largest Piece of Gold; Some Practical Points; A Correction, 214.

SCIENTIFIC PROGRESS.—Theory of Professor Wellner's Flying Machine; Iron Older Than History; Ink Eraser; Miscellaneous, 216.

MECHANICAL PROGRESS.—The Straining of Boilers; Arrangement of Machinery in Power Stations, 217.

ELECTRICAL PROGRESS.—An Important Enterprise in Mexico; The Legal Aspects of Electrolysis; Electrical Terms, 220.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 218-19.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 222.

MISCELLANEOUS.—Concentrates, 211; Electric Power Transmission, 212. A Mammoth Coal Mining Plant; Characteristic Features of California Gold-Quartz Veins, 213-214. Books Received, 214; Timbering in Mines; New Remedy for Insomnia; A Long Life, 221. Patents, 222. Industrial Notes, 223.

DEVELOPMENTS in the Carson mint shortage indicate that the New York bond syndicate are not the only ones who can play a hunco game on Uncle Sam.

SENATOR STEWART of Nevada writes a long letter advocating the organization of "a gold party" and "a silver party" for presidential nominations next year. He can always be counted on to advocate anything that is combative but impractical.

SLOWLY but steadily the hydraulic mining industry of the State is building up again. Three more permits were issued by the Debris Commission this week, making about 75 since that body began its work. With all available hydraulic mines in operation the million a month now yielded from California gold mines would be nearly doubled. Including individual as well as corporate owners it is estimated that there are nearly 150 paying quartz mines now being operated in this State.

THE Governor of Nevada has vetoed a mining bill passed by the recent Nevada State Legislature. It defined a quartz claim as being 1500 feet long by 600 feet wide, and prescribed that in locating a placer claim its dimensions should be those of a quartz claim, "except that where the word 'feet' occurred in such designation it should read 'acres.'" As a placer claim 1500 acres long by 600 acres wide would bring the locator in collision with the federal statutes, and be awkward in other important respects, it is believed the Governor did right in vetoing the bill.

THE long litigation between the English and American claimants of the Amador gold mine, at Jackson, Cal., is at last ended, the ruling and decision of Judge Davis having been sustained by Judge Daingerfield, resulting in dispossession of the American claimants and a writ of possession given J. E. Dye, the financial agent of the English claimants. That being settled the next thing in order is to go to work and develop the idle mine, which has been proved to be a very valuable property. The costly litigation alone evinces that fact.

OF many men and measures it has been said: "The stars in their courses fight for them." According to a grave contemporary, which rarely jokes, the stars favor silver. It says:

> It is a very singular fact that the stars have an indirect effect on the price of silver. The present speculation in silver in India, which is entirely in the hands of native dealers, is chiefly regulated, it appears, by the astrologers, who direct their clients when to buy for a rise and when to anticipate a fall. Of course, in many cases, the fact that their clients follow the advice given them brings about some fulfillment of the prediction, which redounds to the credit of the prophets. Some recent heavy speculative purchasers of silver in London have passed on this kind of advice, and it is said also that the failure of last month's fall in exchange to bring out gold on the Indian bazaars was due to a similar cause.

It probable, however, that the sidereal aspect of the matter is subsidiary to the coarser law of supply and demand.

The Mineral Lands.

The act of July 1, 1862, and July 2, 1864, which donated nearly 100,000,000 acres to railroad corporations, gave the coal and iron land within their limits, but excepted all other mineral lands from the grants. The question of what is mineral land and what agricultural has long been one of argument and litigation. Last year the U. S. Supreme Court, in the case of Borden vs. the Northern Pacific Railroad Co., held that the Secretary of the Interior may determine what is mineral and what agricultural in railroad land up to the time patent issues to the railroad company; but after patent once issues, the matter has passed beyond his jurisdiction and is settled. In accordance with that decision, Secretary Smith issued a general circular referring to railroad selections within mineral regions, providing that wherever a list of railroad selections covered lands located within six miles of any mineral entry, claim or location, publication should be made for sixty days, calling for any claimant to protest against such selection, and in the absence of such protest the land in question was to be adjudged agricultural and a patent issue to the railroad company for such list.

So far as known, the MINING AND SCIENTIFIC PRESS was the first paper to publish this circular or direct attention to its importance, and the danger to any owners of unpatented claims within the regions affected by it; and urgent representation was also made to the miners of California of the need of either securing patents to their claims, and thus forever settling their legal right to the ground claimed, or else to find the exact location of their claims with reference to legal subdivisions and take care to see the railroad company's advertisements when they appeared, and, if their claims were included in the published list, to enter protest at the Land Office. It was also pointed out in these columns that the indirect idea on the part of the Government was evidently to compel miners to perfect their title by securing a U. S. patent, which, where practicable, is the best way.

When the Cal. Miners' Association held their annual convention in November, this matter was brought to their notice and received the fullest attention, none too soon, for already in several parts of the State the railroad company was publishing its lists, lumping whole areas of tens of thousands of acres in a little brief, solidly-set designation by townships without subdivision or any other designation, mostly in some obscure paper, the whole thing taking up only two inches or so among other advertisements, and cleverly designed to attract no attention. The convention appointed a committee consisting of Tirey L. Ford, E. A. Belcher and Chas. G. Yale, who made an elaborate and exhaustive report, being a complete argument from the standpoint of the miner, and which, through these columns, was given wide circulation. When the report was read, it was made the subject of several speeches, and the result was the appointment of a committee on mineral lands whose business it was made to check the action of the railway company till the miners' side of the case could be presented, and permanently prevent the acquisition by railroad companies in this State of unpatented mineral lands within land grant and indemnity land grant limits, it being made the duty of the committee "to appear before the Department of the Interior by memorial and by agent, to endeavor to stop the patenting of mineral lands to subsidized railroads: also to obtain an order from the Commissioner of the General Land Office that the burden of proof that land claimed as agricultural by the railroads shall be placed on those corporations, in accordance with the decision of Justice Field in the Borden case" in Montana. The magnitude of the matter was unusual—the total amount of the S. P. grant alone in this State being 1,638,000 acres—the committee at once began its work, invoked Congressional aid, sent a representative to Washington to secure information, who met with considerable opposition in some unexpected quarters, notably the office of the Commissioner of the General Land Office, whose subordinates seemed to think they were employed solely by the railroad company till they were shown otherwise.

Nearly every newspaper in the State published in a mining community copied the articles from the MINING AND SCIENTIFIC PRESS, the city dailies took the matter up, the committee worked unremittingly, and a degree of publicity was given that was fatal to the secret scheme for success relied upon by the corporation that was trying to absorb so much of the public domain. The committee issued an appeal for pecuniary help that was responded to from many parts of the State, though not as widely nor as freely as was hoped from the 13,000 miners of the State, every one on the committee working without pay; and as fast as the location of the lands could be ascertained, specified protests against the issuance of patent were forwarded to Washington accompanied by such statement of facts and figures as made out a strong case for the miner. With one exception, the entire California Congressional delegation aided materially in this case of the commonwealth vs. the corporation and helped in the securing an order from the Secretary of the Interior postponing issuance of patent for "clear list 54" pending publication, which is now being made in the Monday issue of the Sacramento *Record-Union*. This list shows that in evident defiance of all the legal requirements, mineral land, which by the express provisions of the law was exempted, is included, the railroad selections taking in some of the oldest mining towns and the best known and longest located gold claims, it being solemnly averred that a section of "the Mother Lode;" such towns as Kelsey, Gold Hill, Union Town, Forest Hill, Gold Run, Towles, Colfax; such mines as the Mayflower and West Damascus; such streams as Deer creek, Wolf creek, North and South Forks of the American river, Otter and Canyon creeks; such peaks as McKinstry's and Lola; such lakes as Eureka and Meadow lake," are all—according to "clear list 54"—"agricultural land."

Following the order for the publication of this list came withdrawal of list 22 in the Los Angeles district and list 25 in the Redding and Marysville districts, and a general suspension of Government haste in the matter showed that the Commissioner of the General Land Office was not the sole arbiter in the matter as he assumed to be at the outset when he refused access to public records in his office.

A similar effort to absorb fifteen townships in Trinity, Sbasta and Siskiyou Cos., by technical compliance with the letter of the law in inserting a brief notice in the Scott's Valley *News*, was also discovered and ventilated, and so far the effort has been checked. Miners in various counties have also been active in making individual protests at the Land Offices, in addition to the general protests on the part of the committee, and such general vigilance exercised as to bring to a standstill the governmental railroad machinery that was so rapidly placing the land in question in such shape that miners and prospectors would have to acquire title to that part of the public domain from the railroad company.

In all this there has been no petty hostility or effort at annoyance or desire to withhold any one's just right. It is recognized that the railroad company have certain rights to certain lands; in these rights the company deserves and should have the same exercise of justice as any other citizens; no more, no less; all the miners ask is that their rights be not interfered with, and being crowded pretty close, they are making a determined fight. Sometimes peace is so valuable that men must fight for peace. So in the present instance. There isn't a miner in the State who wants to see the S. P. Co., or the C. P. Co., or any other company, railroad or otherwise, beat out of an acre rightfully theirs; but in assuming that mineral land is "agricultural land," and trying to grab mining claims and mining towns, the corporation has evoked a spirit of determined resistance that asks only for justice; for what is right and lawful; and that has no apology to make for being right, but says "Hands off, or take the consequences." It is to be noted that several thousand acres in this State, avowedly mineral land, has been held by the railroad company under agricultural patents, and that the miner has been compelled to secure title to such land from the railroad people, this, as other things, in contravention to anything contemplated by law.

From the start, the MINING AND SCIENTIFIC PRESS has also directed attention to one fact which at any stage of the conflict, or in the absence of any conflict, should not be overlooked—for every reason it

is well if at all practicable for every miner or claim owner to get a U. S. patent for it; then if he wants to hold it, no man or men can bother him; and if he wants to sell it, nothing, not even the value of the gold in it, will help the sale so much as to be able to say, "I have a U. S. patent for this." Mine buyers like nothing better than a clear title: they dread nothing so much as a lawsuit.

Meanwhile, to return to the subject, the work goes on. The executive committee of the California Miners' Association met last Tuesday night and decided to send A. H. Ricketts, the chairman of the mineral land committee, to Washington to personally see the President of the United States, the Secretary of the Interior, the Commissioner of the General Land Office, and make such showing as will be fully explanatory of the justice of the position assumed by the miners of California and endeavor to secure suspension of all proceedings in patenting public lands within railroad grant limits in this State till Congress meets next December and can take action on the classification bill introduced in the closing weeks of the 53rd Congress. Mr. Ricketts leaves next Tuesday and will be absent several weeks.

MR. HENRY T. SCOTT, of the Union Iron Works, president of the Manufacturers' Association, in an interview in last Tuesday's *Examiner*, says some things that are strictly business and strictly true. For instance: "We should cultivate the Chicago spirit—the spirit that fills the people of that city with the belief that anything made in Chicago is better than the same thing made anywhere else. It has been the habit here to believe that nothing could be really good unless it were made at a long distance from our homes." Mr. Scott characterizes it as a "habit." That's just what it is. That habit pervades all our people, urban and rural, and not till its tendency is more clearly realized will the business pendulum start to swing the other way.

IN happy contrast to the whimpering pessimism of some publications, the *Engineering Magazine*, in its current number, devotes a page of its advertising space to a sworn statement of its business, signed by its manager, in which it appears that in the month from January 10th to February 10th, '95, there were received 952 new regular cash-paying subscribers, and that, in addition to all current renewals and transient orders for advertising, there were received during January advertising contracts aggregating $2888. The statement has every appearance of truth, and is a good index to improved conditions in the industrial world, in many branches of which the *Engineering Magazine* is an able exponent and impartial review.

REGARDING the enormous demand for mining machinery in South Africa, a Johannesburg correspondent of *Machinery* (published in London) estimates that within a short time 1000 additional stamps "of heavy and improved type" will be working. In some of the deeper mines the number of stamps required is estimated as follows: Geldenhuis 200 stamps, Nourse 150, Crown 250, Langlaagte 250, Rose 150, Robinson 150, Village Main Reef 100 and Simmer and Jack 250.

THE Sacramento *Record-Union* sensibly and justly opposes what is usually known as a "write-up." The "write-up" was done to death years ago, and is valueless. Its appearance is detrimental to whatever is "written-up," and the money paid is worse than wasted. The paid "write-up" should go with the "coupon," "premiums," and other journalistic attachments.

J. S. LEEDS, manager of the Traffic Association of San Francisco, has resigned his $10,000 position, saying that it no longer has need of his services, and returns to his home near Cincinnati, O.

HON. JAMES G. GRANT, formerly Governor of Colorado, and now one of its foremost mining and smelting men, has been selected as chairman of the Exposition of Mining at Denver in 1896.

A NEW coal mine has been discovered within seven miles of San Bernardino. The vein is twenty inches wide and runs for miles. A company is forming to open up the find.

Concentrates.

NEVADA people fear that the Carson shortage may shut down the mint.

THE Horn Silver, Utah, mine paid a 12½-cent quarterly dividend last Monday.

THE Blue Bells, during the past 90 days, has shipped 8000 tons of ore to the Pilot Bay smelter. Besides silver it is said to carry 1¼ per cent in nickel.

THE Blue Mountain Mining Company has incorporated at Haines, Oregon. Capital stock, $200,000; incorporators, D. Wilcox, G. H. Taney, C. F. Hill.

THE *Ledger* asserts that S. W. Bright has arranged the sale of the Bellwether mine in Jackson district, Amador Co., to New York capitalists for $110,000.

BY an adverse majority of 59, Grass Valley citizens decided last Tuesday that they did not want to bond the city for $50,000 for forty years to build sewers.

THE action of Samuel W. Allerton, of Chicago, against the Homestead Mining Company, in South Dakota, to recover $200,000, has been dismissed.

A PETITION has been filed by the stockholders of the Linderaxa Mining Company for the removal of the principal place of business from Mokelumne Hill to Berkeley.

THE Debris Commission last Monday granted hydraulic permits to the Mooney placer mine, the Black Lock mine, near Placerville, and the Grizzly Flat mine in El Dorado county.

MRS. PRICE'S interest in the Colorado mine, Minas Prietas, Mexico, is reported sold to the Chamberlin interest for two million dollars, and J. N. Jones will be manager of the property.

AT Pilot Bay the smelter is shipping a carload of bullion a day. The ore treated is chiefly from the Bluebell mine on the shores of Kootenai lake. Thirty-five men are at work in the mine.

THE Apex-Albambra Mining Company has incorporated at Salt Lake with capital stock $27,000. The company owns the Apex, King Solomon and Alhambra mining claims in Millard county.

THE Nevada *Herald* learns that the Badger Hill Mining Co. are negotiating the sale of their property to Grass Valleyans. The mine is looking well, and is considered a valuable property.

PROFESSOR BLIVENS of Okanogan, Wash., says that his new process is now entirely covered by caveats and patents, and that it will be impossible for any one to infringe on his valuable rights.

LEIGH HARNETT, who has been investigating the mineral resources of Josephine county, Oregon, says there are between sixty and seventy placer mines in full operation there, with more to be opened soon.

THE Mariposa Power and Mining Company has incorporated. Directors—W. B. Lee, F. E. Hentrich, P. T. M. Wate, G. E. French and J. M. Duncan. Capital stock, $200,000, of which $500 has been subscribed.

ALFRED L. WEST fell from a skip in the shaft at the Golden Gate mine in Sonora, at the 300 level, last Tuesday, and was instantly killed. His body was found between the 400 and 500 levels, his head being crushed to a jelly.

THE brick vault at the Nevada Reduction Works, near Reno, in which quicksilver and other articles were stored, was recently entered by burglars, who stole twelve flasks of quicksilver, containing about seventy-six pounds each.

COOK & BRUEN, of Denver, have bought one-half the Yankee Fork, Idaho, mine, and expect to treat the ore at a cost of milling not to exceed $2.50 per ton. A twenty-stamp mill will be built and considerable other machinery put in.

THE Interior Development Company, which lately purchased the property of the Amador & Sacramento Canal Co., are preparing to reopen the old Sebastopol mining ditch. Two thousand feet of twenty-inch pipe is to be laid across Arkansas creek.

SENATOR TELLER, of Colorado, is quite proud of a new paper weight which has been given to him. It is a block of standard fine silver, inscribed "Sixteen ounces Colorado silver," upon which is fixed a block of gold, inscribed "An ounce Arizona gold."

R. W. GRAYSON has filed a protest against the publication of lists of proposed railroad land grants clear listed in the Redding and Los Angeles land offices, showing that the publication of the lists was not in conformity with the requirements of the department.

C. B. HOFFMAN, of Montana, is either a very lucky or a very unlucky man. Last spring his clothes were torn off of him by lightning, at the Glengarry mine. Last Wednesday he fell thirty-five feet down the Glengarry shaft and came up unhurt except a few scalp wounds.

THE *Mining Review* says that the case of the Rico-Aspen vs. the Enterprise has not been finally decided, but that the effect of the recent St. Louis ruling was simply to remand it back from the U. S. Court of Appeals to the original court for further hearing upon questions of fact.

GOV. JONES, of Nevada, has vetoed Assembly bill 95, relating to the locating, recording and working of mines, on the ground that its provisions in making new and unusual requirements for locating lodo and placer claims are inconsistent with the mining laws of the United States.

THE English quartz mine, near Cherokee, Nevada Co., was bonded last Tuesday to John M. and Fred J. Thomas, of Grass Valley. A mill is to be put up and 300 feet of new flume will be built. The purchasers intend to work the mine thoroughly and will put on as large a force as possible.

THE cement crushing mill at the Kate Hays mine, French Corral, is to be moved to Badger Hill, near Cherokee, says the Nevada *Transcript*, where it will be put up and used to crush the gravel and cement found in the Milton Company's claim at that place. The mill will be erected on the old Badger Hill claim.

AN investigation of the practical value in gold production of the black sand existing along the coast of Washington and Oregon is to be made at North Head, Wash., just north of the Columbia river, under the direction of David T. Day, chief of the division of mining statistics and technology of the United States geological survey.

"AFTER a fruitless effort to make their scheme a success the gold miners at the Ocean House beach have suspended operations. The dust extracted from the black sand does not pay more than fifteen cents per ton, according to their calculations. The machines used for amalgamating purposes at the scene of operations have all stopped running, as the best of them cannot clear more than ninety cents per day." The above, from a daily paper, is the latest from the annual bonanza discovered in that vicinity.

DIRECTOR WOLCOTT, of the U. S. Geological Survey, proposes to place Drs. Becker and Dall in charge of an investigation of the coal and gold resources of Alaska. They will leave Washington next month, go to Sitka via this city, thence to Kadik, Cook's Inlet and Unga Island, returning about August 1st.

THE Gertrude Gold Mining Company incorporated at Spokane, Wash., is capitalized at half a million dollars: purpose to own and operate mining properties in the United States and British Columbia, together with mills, smelters, concentrators, etc. The trustees are C. P. Oudin, A. Beamer, A. B. Railton, F. D. Gibbs and F. W. Gibbs.

A MAN named David Crisman was found in an abandoned tunnel, near Winnemucca, Nevada, last Sunday, nearly dead from starvation. He claimed to have been in the tunnel a month without food, and nothing but snow water to drink. When taken to Winnemucca and placed in the hospital, he had wasted away to skin and bones, and it was doubtful whether he would live.

CAPTAIN PARKER believes that the plan which he originated some time since, of dredging the rivers and bays of Coos county for deposits of gold-bearing black sand, is feasible. While on Coos bay he informed the *News* that he will visit that place in the near future. He has perfected a machine which will handle 2000 tons of sand per day with a working force of only three men.

THE new DeLamar, Nevada, mill started up last Tuesday. A 100-horse power electric hoisting plant has been ordered by Captain DeLamar for the DeLamar Company. The cars in the tunnels will also be operated by electric power. About 300 feet east of the mill a tunnel has been started to tap the mines of the DeLamar Company, at a greater depth than any of the present workings.

LEAVING out the islands, the central point of the North American continent is in longitude 116 deg. 17 min. West, and latitude 40 deg. 30 min., or in the neighborhood of Elko, Elko county, Nevada. Including all Uncle Sam's dominions, the central point between Eastport, Maine, and Attou, Alaska, would be in the Pacific ocean, about 34 miles due west of the mouth of the Columbia river.

W. T. HART, a Montana representative of capitalists, has bonded property in the Slate Creek, Wash., district covering several groups of mines, for an amount aggregating $500,000. Forty men went to work developing the property last week. Thirteen tons of steel tools form part of the outfit. The men will have hard sledding for a while, as there was fifteen feet feet of snow on the claims a month ago.

THE contract for the construction of the Parrot Mining Company's ditch has been let by the Parrot Company to Winters, Parsons & Boomer of Butte, Montana. The ditch will be 18 miles in length, from 15 to 30 feet wide and 5 feet deep. It is for the purpose of conveying water from the Jefferson river to the site of the new smelter to be erected by the Parrot Company five miles from Whitehall in a few months.

THE Baker City, Or., *Democrat* says most of the old miners around there who have been holding onto their properties for years expecting to become millionaires seem to have come to the conclusion that to bond some of their prospects and have them developed would be a pretty good idea. There are too many mines lying idle these days on account of their being held and owned by parties who expect to make sales and make money without working for it.

SAM'L MCINTYRE, in his report to the directors of the Mammoth Mining Co., of Utah, charges some of the officers of the company with complicity in an alleged over-disbursement of $127,521.20. He says $84,888.15 more than was necessary was spent for the new mill, and that nearly $80,000 was lost in the treatment of ores. The officers censured say that his figures are made up almost wholly from erroneous estimates and that his allegations have no foundation in fact.

THE Supreme Court has decided the case of Alvord et al vs. the Spring Valley G. M. Co., reversing the decision of the lower court from which appeal was taken. The gravel mine at Cherokee, Butte Co., was the property in dispute. When the bondholders started to foreclose the mortgage given in '81, other creditors of the mine—the Bank of California, N. D. Rideout and C. Waldeyer—intervened, claiming that the mortgage was illegal, not having been authorized by two-thirds of the stockholders of the then New York corporation. Judge Prewett in the Superior Court decided that such view was correct; that the mortgage was not technically flawless. The Supreme Court now reverses that decision and sustains the legality of the bond issue, and the execution of the mortgage.

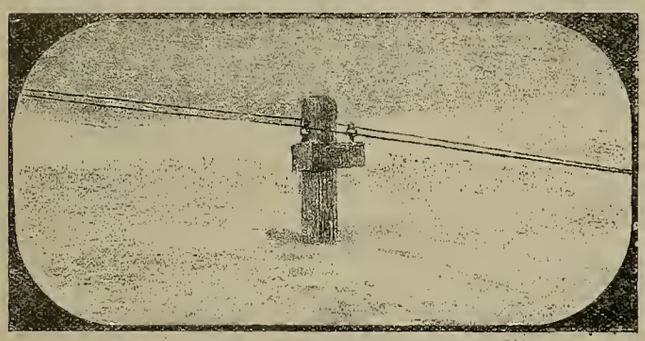
MONTANA prospectors who locate claims after July 1st in that State should remember that to make a new quartz location after that date the prospector must sink a hole at least ten feet deep to solid formation, must have at least one well-defined wall, and the stakes must be placed so they can be found. Under the new law the notice of location cannot be placed on a stump or a tree adjacent to the claim, but must be posted in a conspicuous place at the discovery shaft. He is allowed ninety days to sink the required depth and record the claim. If an old claim is relocated, he is required to sink it at least ten feet deeper than when he first found it, and stake and relocate it as though it was an original discovery. If he runs a tunnel it must be at least ten feet long, so as to determine the fact that a vein supposed to carry precious metals has been discovered.

AT a meeting of the Executive Commitee of the California Miners' Association last Tuesday evening in this city, the San Francisco Board of Trade handed in its check for $1000 as its first contribution to aid in protecting the mining interests of the State. A resolution was adopted looking to the appointment of an agent at each mining town in the State to issue certificates of membership on the payment of $5. A motion was adopted that an assessment be levied on the county associations equivalent to fifty cents a member, the amounts already contributed to be credited thereon. The sum of $2000 was voted for the expenses of Mr. Ricketts' trip to Washington. It was ordered that a financial statement be prepared, showing receipts and disbursements of the association to date. Mr. A. H. Ricketts was appointed to proceed to Washington, visit the heads of departments, the President and others, and make such a showing of the facts in the case as would aid in preserving the mineral lands of the State from absorption by railroad corporations.

Electric Power Transmission.

(Concluded from last issue.)

The line has given no trouble whatsoever, and has carried the high potential of 3000 volts without a leak, even during a severe storm of ten hours' duration, the rain changing to sleet and ice toward the end; but the severe test, it must be admitted, occurred after the wire had been wrapped at the insulators as described. In fact, one of the chief objects of this insulation was to render the line proof against just such a storm as this. Snow-storms have no effect whatever, as will be observed by reference to the illustration "Pole No. 40."

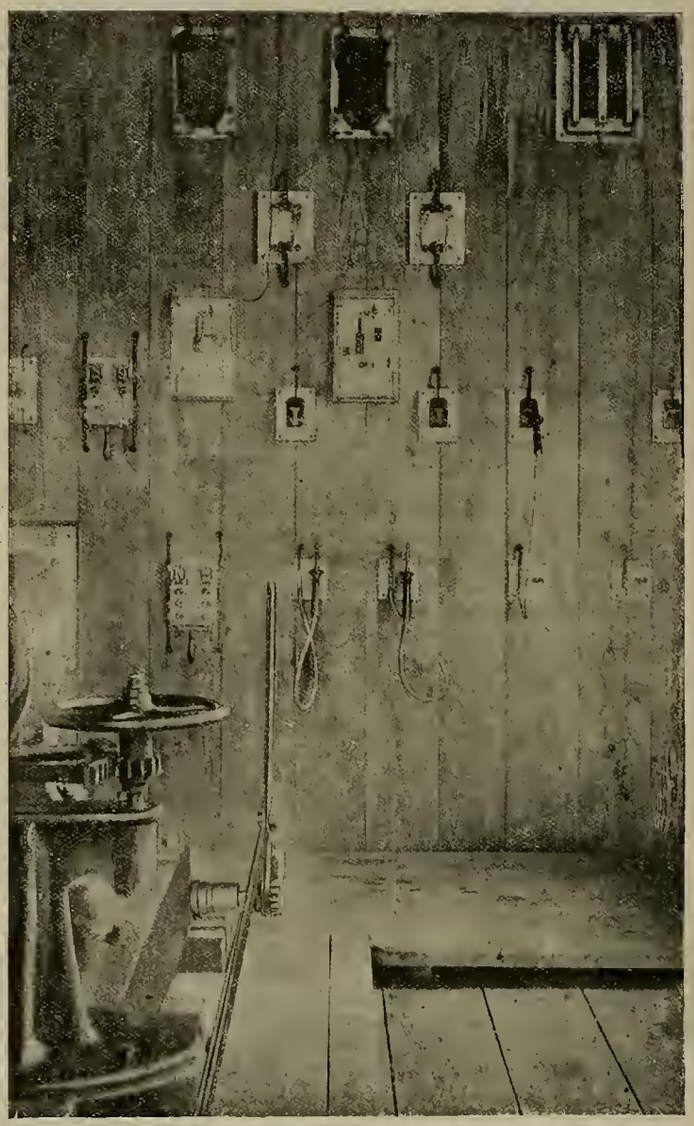


POLE NO. 40: 4000 FEET FROM MILL.
(Wire is 17 ft. above ground at pole; snow 15 ft. deep.)

The motor that drives the stamp mill of the Standard Consolidated Mining Company at Bodie is an A. C. synchronous constant-potential machine of 120-horse power, illustrated below in operation. The mill contains twenty 750-pound stamps, four wide-belt (6-ft.) Frue vanners, eight continuous-process amalgamating pans (two of which are constantly grinding), three settlers, one agitator, one pan and settler devoted to the amalgamation of concentrates, a bucket elevator, a worm-gear hoist, and a rock-crusher. In order to determine accurately the capacity of motor required, a number of cards were taken with the Tabor indicator from the 20 by 36-inch steam engine that drove the mill, showing an average of 90 and a maximum of 101½-horse power.

The fields of the motor are self-exciting through a secondary winding on the teeth of the armature, the current being led to a twelve-bar commutator similar to that on the generator. In fact, the motor is almost identical with the generator, the chief difference being in the compensating-winding on the field-bobbins of the latter.

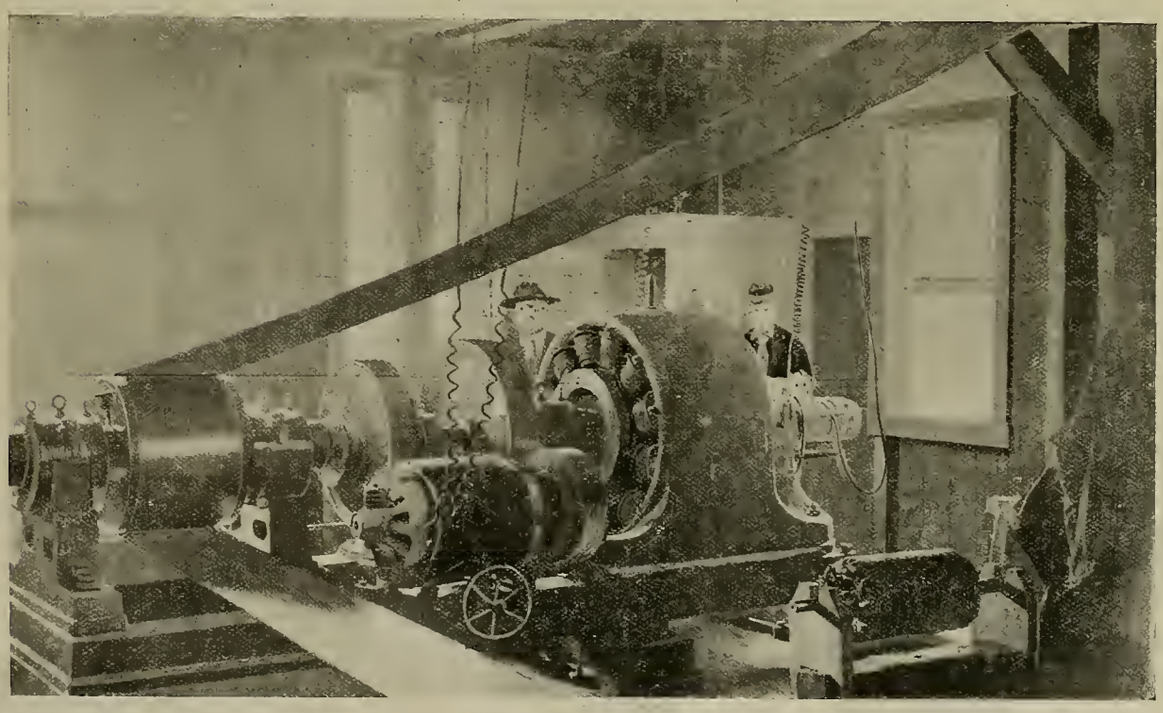
On the armature shaft of the motor is a friction-wheel, and beyond this a clutch, which is used to set in motion the driving-pulley and the machinery of the mill. On the same bed-plate with the motor is a small 10-horse power Tesla starting-motor, with a wooden pulley on its shaft, that is brought to bear against the friction-wheel mentioned, by means of a screw and hand-wheel. This Tesla motor consists simply of field-coils and an armature; it has neither brushes, nor commutator, nor sliding contacts of any kind. The alternating current is led directly into the fields, the stationary element, the coils of which, being connected in series, produce a rotating magnetic field, in which each pole is alternately positive and negative. The starting-torque of the armature is, in consequence, very low, and it has to receive several rapid turns by hand before putting on the current, after which it generally runs up to normal speed (1660 revolutions) within a minute. In the switch-board, as shown herewith, the two plugs in the sockets on the right of the board are the line-plugs, and the two to the left of them, in their rests, are the starting-motor plugs. When the line-plugs are in their sockets the current is led directly to the top of the upper jaw-switch, and this switch is never closed until the machines are in synchronism. The wires from the bottom of this switch lead directly to the collector-rings on the armature-shaft of the motor.



MOTOR SWITCH-BOARD.

In the upper right-hand of the board is the Wurts lightning-arrester, consisting of 22 spools, 11 on a side, separated each by a distance of $\frac{1}{32}$ inch. Both legs of the wire-line are attached to the arrester, one on each side at the top, while the ground-wire leads from the bottom spools to a water pipe in the earth. The spools are made of a patent non-arcing metal, and the dynamo current will therefore not follow the path through them made by a discharge of high-tension atmospheric electricity. The properties of this alloy are such that oxides of the metals are generated by the passage of lightning and not vapor of the metal itself.

To the left of this instrument are two converters of the ratio of 30 to one, filled with paraffine oil. The primary coil of the right-hand one is connected to the main line just above the plug-sockets, and that of the left-hand converter is connected to the motor-circuit, *i. e.*, the wires reading from the collector-rings on the armature-shaft to the bottom of the upper jaw-switch; it being understood that the motor acts as a generator when being driven by the starting-motor. To start the motor requires two men, one to handle the starting-motor and the other at the switch-board. The line-plugs are put in, which leads the main current to the top of the synchronizing-switch, and the lower jaw-switch is thrown in, which closes the field-circuit of the motor, and the secondary of the main-line or generator converter, thereby lighting the upper lamp of the synchronizer. The armature of the starting-motor is turned a few times by hand, and the two left-hand plugs are then pushed into their sockets, leading the current from the main line to the fields of this motor.



MOTOR IN OPERATION, STANDARD CONS. MILL.

As soon as the armature is above speed, about two-thirds of the rheostat is thrown out, permitting 40 or 50 amperes of current to flow, and the lower lamp of the synchronizer to burn. The pushing onto its button of the little switch on the bottom of the synchronizer now connects the two central lamps in series with the motor and generator currents, and they begin to flash in accordance with the phases, and therefore the speeds, of the two machines. As the speed of the motor approaches that of the generator, the wave-phases come nearer coincidence, and these lamps brighten and darken almost simultaneously.

The attendant stands with one hand on the rheostat and the other on the open jaw-switch, watching these waves of light intently, and just as the two lamps darken in unison, he throws in the switch and pulls one of the starting-motor plugs. The lamps only remain

"out" for a second or less, while the speeds are together, and then flash up brightly again as the motor speed drops off: there is therefore but a fraction of a second during which the jaw-switch should be closed, though the time can be lengthened slightly by a proper handling of the starting-motor.

If this switch has been thrown in at the right moment, the series lights remain "out," while the top and bottom, or "pilot" lights, burn brightly, and so continue all the while the machines are in operation.

The entire operation of starting up the motor from a state of rest occupies from three to five minutes, and when once in synchronism, the clutch can be thrown in and the mill shafting brought to normal speed in from one to two minutes more, after which the load may be thrown on as fast as desired without the least danger of pulling the motor out of synchronism. The clutch is always thrown in slowly in order to prevent too heavy a flow of current, and consequent sparking of the commutator brushes.

By means of a single counter-shaft, fitted with self-oiling boxes, the high speed of the motor, 860 revolutions, is reduced to the necessary 80 revolutions of the battery line-shaft, the reductions being 2 ft. to 8 ft., and 3 ft. to 8 ft. Light steel-rim balanced pulleys are used, and an endless 16-in. double leather belt runs from the motor to the first 8-ft. pulley. The speed of this belt is 5400 ft. per minute, and it is kept tight by levers which, acting through screws, move the entire motor and its bed-plate along four grooved, cast-iron slides.

The motor is separated from the underlying brick foundation by means of 8 by 10-in. timbers, which are bolted to the latter and covered by three layers of 1-in. boards; and to this wood insulation the slides referred to are fastened by lag-screws that pass through the boards into the timbers. The generator is insulated from the I-beams that carry both it and the water wheels, by timbers 5½ in. thick, to which it is likewise secured by lag-screws.

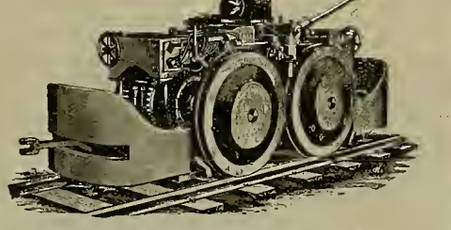
The mill and offices of the company are lit by 100-volt incandescent lamps, taking current from a large 100-light converter, ratio 30 to 1, which is attached to the main line in the motor-room, before it reaches the switch-board. The light is very satisfactory, even to read or write by, although at times the lamps flicker slightly, due to changes of load.

The entire cost of this plant did not exceed $40,000. Its operation during the month of October, 1893, alone effected a saving of $2100, equivalent to $1.46 per ton of ore crushed, and reducing the total milling cost to $2.32 per ton; a fairly low figure for a high-priced camp (wages $4 per day) such as Bodie.

The plant runs smoothly, and demonstrates the effectiveness and simplicity of the single-phase synchronous system for such work and distances, while the daily saving over the use of steam, on twelve-hour runs, is from $35 to $40.

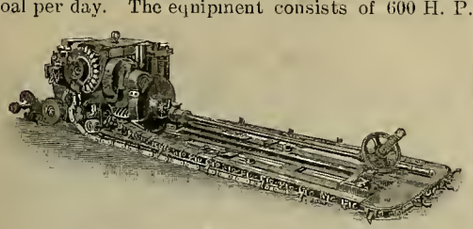
A Mammoth Coal-Mining Plant.

As a matter of indirect interest to this coast it is noted that the Essen Coal Co., of Pittsburg, have just closed a contract for a complete electric plant for mining and hauling the coal in their No. 2 and No. 3



80 H. P. ELECTRIC LOCOMOTIVE.

mines at Hazeltine, Pa., being the largest plant ever considered for bituminous mines. It will cost $80,000, and is intended to produce 2400 tons of mine run coal per day. The equipment consists of 600 H. P.



CHAIN BREAST MACHINE.

in boilers, three 200 H. P. engines, three 150 K. W. dynamos, two 80 H. P. locomotives, station equipment and circuits, and sixteen chain breast machines. The electric locomotives and breast machines are herewith illustrated.

EXPORTS of mineral oils from the United States for February were 60,639,199 gallons of a value of $3,161,396, against 55,803,469 gallons of a value of $2,646,019 for the same month last year.

Characteristic Features of California Gold-Quartz Veins.

NUMBER II.

Read before the Geological Society of America by WALDEMAR LINDGREN, December 29, 1894.

The typical gold-quartz veins cannot be considered as anything but fissures and fractures filled with quartz, accompanied by small amounts of native gold and metallic sulphides. Replacement proper of the minerals of the country rock along the fissure by quartz I have never been able to observe, and causes supposed to be of such nature have always proved to be due to the shattering of the country rock and the filling of it by silica along narrow cracks. The clean quartz usually forming the vein I cannot account for in any other way than by filling of cavities, as it does not seem possible that a replacement of the ferro-magnesian silicates and other minerals could occur without leaving chloritic stains or other signs in the resulting mass. In all quartz veins of this type it seems unavoidable to admit the existence of open spaces along the vein, supported at frequent intervals by the contact of the two walls or by rock fragments. Even the heaviest veins show in the underground workings frequent places where the walls "shut down." Such fillings of clean quartz may vary in width from a few inches to several feet. "Horses," of course, frequently appear in the larger veins, separating them in two or more parts. The heaviest veins appear to be found along the mother lode in Tuolumne and Mariposa counties, where the clean quartz often reaches a width of ten to fifteen feet, and in isolated cases even more. This extreme thickness seldom continues for any great distance. It may probably be safely assumed that gold-quartz veins of this type cannot be formed at any extreme depths below the surface, probably not below 10,000 feet, for at such depth open spaces could hardly exist. These very large fissure veins are, however, not very abundant; a moderate width of one to three feet is far more common. In many cases, indeed, there are no large open spaces at all, but a network of smaller cracks and fractures in which the solutions deposited their contents.

In the predominating milky white quartz of the veins but few other gangue minerals are found. Calcite, more rarely magnesium carbonate, or a mixture of both, occur occasionally, but always in subordinate quantities and usually concentrated near the walls. The quartz is ordinarily massive, but excellent examples of comb structure may be found. Barite and fluorite are conspicuously absent. A white mica with pearly luster is sometimes found in the quartz at some of the mines along the mother lode, and a green potassium mica, colored by chromium, and which Professor Silliman has called *mariposite*, occurs abundantly in places, though usually not in the quartz itself. Roscoelite, a vanadium-potassium-mica, has been found in one place, and albite occurs in isolated cases. Rhodonite has been found in Plumas county. Titanium minerals, such as titanite, ilmenite and anatase, occur occasionally.

The native gold is distributed through the quartz gangue in an irregular manner. The particles may be of microscopic size, or coarser, and visible to the naked eye as scales, threads and smaller masses. Occasionally large pieces, of all weights up to fifty pounds or more, will be found. In the ores from the larger mines it is, however, rare to find the gold visible to the naked eye. The gold always contains a little silver, in rare cases as much as thirty per cent.

A variable but always comparatively small quantity of metallic minerals accompanies the gold. It varies from a fraction of one per cent to five or six per cent, but ordinarily makes up from two to three per cent of the mass of the quartz. Sulphides are most common, but compounds of arsenic, antimony and tellurium also occur. A list of the associated minerals in the quartz veins would include the following species:

Iron pyrites (universally present).
Pyrrhotite (not common).
Copper pyrites (common).
Zinkblende (common).
Galena (common).
Molybdenite.
Arsenical pyrites (common).
Tetrahedrite.
Antimonial lead sulphides (rare)
Cinnabar (rare).
Tellurium minerals—Hessite, Altaite, Calaverite, Sylvanite, Petzite, Melonite (frequent, in small quantities.)
Nickel and cobalt minerals (very rare).

Marcasite is noticably absent from gold deposits, as noted by Mr. Louis. I have once seen it, however, from a mine at Grass Valley.

These metallic minerals, usually referred to as "sulphurets," contain more or less gold and silver and are frequently very rich, the concentrates ranging from thirty to several hundred dollars per ton.

Bismuth and cadmium have been found in small quantities in concentrates from the Nevada City mines, the former also in Shasta county. Compounds of tin, wolframium, uranium, boron, phosphorus and fluorine appear to be entirely absent. Cuprite, bornite and chalcocite are also lacking. Cobalt and nickel minerals are occasionally present. Titanium occurs sparingly.

A slight influence of the wall rock upon the character of the mineral association cannot be denied. It appears to be a fact that veins in granodiorite contain more sulphurets than those in other rocks. Pyrrhotite appears to be entirely confined to veins in this rock. It is known only from the vicinity of Washington, in Nevada county, Sonora, in Tuolumne county, and Westpoint, in Calaveras county. Veins in black sedimentary slate or on the contact between greenstone and slate seldom contain much besides iron pyrites, and perhaps arsenical pyrites; neither are veins in augite-porphyrite or diabase usually rich in sulphurets. Veins in gabbro often contain copper. These are no strict rules, however, and the influence of the wall rock may, on the whole, be considered as remarkably small.

Gold is universally distributed in the quartz veins of California. The definition of what is ore, or quartz paying for exploitation and metallurgic treatment, will necessarily vary at different times and in different places. Under exceptional circumstances, rock containing as little as one or two dollars of gold to the ton will pay. In the deep mines the tenor of the extracted ore is usually from five to twenty dollars.

In wider veins a small streak near one of the walls will sometimes contain the pay, while the rest is comparatively barren. Equal distribution of value in cross-section is, however, common enough. Considered in projection on the plane of the vein, there is rarely an equal distribution of the gold over large surfaces. The richer ore is concentrated in bodies and masses, which sometimes may be wholly irregular, but which usually show more or less regular outlines. These richer masses are called chutes or chimneys, and appear on the plane of the vein in long-drawn linear or elliptic form, with a dip which usually is above forty-five degrees. Flat ore chutes occur, however, as, for instance, in the Idaho mine, Grass Valley. Their width ranges from a few feet up to several hundred, and their length may exceed 2000 feet. It is not uncommon to find one of these ore chutes give out in depth, but another chute will then probably be found in some place below it, if a thorough exploration is carried out. It is a practical rule in many districts, and one which holds good in a remarkable number of cases, that the chutes dip to the left when one is standing on the apex and looking down along the dip. The explanation of the ore chutes is difficult. They may, as F. Posepny and others have suggested, simply indicate the direction of least resistance for the gold-bearing solutions. This explanation is not entirely satisfactory, for in the intervals between the chutes it is by no means the rule to find the walls shut down tight. On the contrary, it is common to find the barren vein between them as wide, if not wider, than the rich vein in them. An increase in the quantity of the sulphurets always accompanies the increase of gold in the ore chutes.

No gradual decrease in the tenor of the ore takes place with increasing depth; on the whole, the character remains constant. Individual ore chutes may be exhausted, but others, as a rule, are found below them.

Certain veins show no large bodies of milling ore at all, but coarse gold concentrated at certain points; such deposits are called "pocket veins." Small seams may sometimes carry a surprisingly large amount of gold. Intersection of seams or veins often, but by no means always, produce pockets or ore chutes.

The study of the changes and alterations which the rocks adjoining the fissures have undergone is a subject of the highest importance, for in this way a closer insight into the genetic processes of the vein may often be obtained.

It would at first glance seem more likely that the rock in the vicinity of the quartz-filled veins would have undergone a silicification. Such is not the case. Instead of silicification there is, as a rule, a most marked carbonatization, or a conversion of the country rock to carbonates. Most intense next to the vein, the alteration gradually decreases at a distance from it, the width of the altered zone varying according to the width of the vein. The carbonate zone, surrounding the quartz vein on both sides, may often be studied to great advantage in small veinlets cutting through hand specimens.

This action upon the adjoining country rock is in itself, to my mind, the strongest possible evidence against the application of lateral secretion in its narrower sense to these veins. It appears to completely refute the theory of the veins being formed by percolating surface waters, and prove the existence of an ageney active in the fissures and gradually extending outward.

The solutions circulating in the fissures acted with different intensity on different rocks. Nearly all igneous rocks, acid or basic, are profoundly altered, the latter more than the former, and serpentine more than any other. Only extremely silicious rocks, and especially certain carbonaceous slates, appear to successfully withstand the action of these solutions. The process of carbonatization has not in all cases been carried out to its full extent; in some veins it is more marked than in others; occasionally fresh rock may lie close up to the vein. Crushing of the rock next to the vein facilitates the process and increases the width of the altered zone, which may vary from a few inches up to twenty feet, and even more in exceptional cases. With all variations,

there is no doubt that the process is a general one, and characteristic for the type.

The result of the process, when it has been thoroughly carried out, is the conversion of the country rock by replacement to a mixture of carbonates, white potassium-micas (sericite), a small amount of chloritic minerals and residuary quartz; besides, there is always a large amount of iron pyrites, usually more than in the vein. Arsenical pyrites is also frequently present, but never, as far as I know, any other sulphides in noticeable amounts. Calcium carbonate usually prevails, but the carbonates of magnesium, iron and manganese, are also present. According to numerous analyses, calcium is always added, while nearly all of the sodium is carried away. The potassium of the orthoclase remains transferred to the sericite. As abundant potassic micas are often found in wall rocks originally very poor in this metal, it is probable that some potassium was also added. In silicious rocks the quartz is often attacked, but never completely carried away. The iron ores, and partly also the bisilicates of the original rock, appear to have been converted into pyrites, while the titanium in it was transformed to leucoxene.

In the case of clean-cut fissures, with well-defined quartz veins, it is usual to find by far the largest amount of gold in the quartz and in the sulphides associated with it. The altered country rock is not entirely barren, but it does not often contain native gold, and its sulphides are much poorer than those in the quartz. This is not entirely without exceptions, for in several places, usually adjoining rich chutes, the altered country rock will pay for milling, and may, in isolated cases, go as high as $12 per ton. And again, there are cases in which the altered country rock is traversed by a great number of minute quartz seams, in which the gold is concentrated. Such a case is the Rawhide mine, Tuolumne county, in which this altered and fissured country rock is far richer than the main quartz vein. At the same place the gold sometimes also penetrates and coats the cleavage faces of the adjoining talcose or serpentinoid schistose rocks. I have always found such occurrences to be more or less altered rocks from the immediate vicinity of some vein. The gold occurs on minute, sometimes hardly visible, seams traversing them. Indeed, many fissures are absolutely microscopic.

It has been stated above that serpentine is peculiarly liable to alteration by the auriferous solutions. The zones of altered rock are in this case often very large and always very characteristic. They may be twenty or thirty feet wide, or, in the case of branching veins, a whole area, several hundred feet across, may be more or less completely altered. The serpentine is converted into a mixture of magnesic and calcic carbonates, a green micaceous mineral containing potassium and colored by chromium, to which the name of mariposite has been given by Professor Silliman, together with more or less iron pyrites. The altered mass is frequently shattered and traversed by seams of mixed quartz and carbonates. It has a rather coarse, crystalline structure, and a bright green color from the disseminated mariposite. The carbonates referred to as ankerite by Professor Silliman are in reality, as indicated by H. W. Fairbanks, a mixture of varying composition, ranging from calcite to magnesite, and often containing considerable iron. Magnesic carbonate, on the whole, predominates. The mineral mariposite is, as Silliman observes, only associated with magnesian and chloritic rocks. Fairbanks states that it is particularly characteristic of the mother lode. This is not correct. It is, however, eminently characteristic of all quartz veins in or at the contact of serpentine, though occasionally occuring in very small quantities in diabase and other basic rocks. The writer has noticed the same characteristic mixture of carbonates and mariposite from a great many places in the gold belt besides the mother lode; thus, for instance, at the Phœnix and Red Chief mines in Sierra county, and also near Washington, Nevada county. It appears at the mother lode wherever that great quartz vein breaks through serpentine. Quartz mountain, Tuolumne county, is an excellent place to study it.

(To be Continued.)

A Correction.

To the Editor:—In your issue of the 16th inst. you give a summary of the interesting discussion regarding the molecular change which takes place in stamp stems; in the opening sentence you quote me as saying that "vibration under all conditions will crystallize iron." These words are Mr. Argall's, not mine. In my "Limitations of the Stamp Mill", I confined myself to the condition of iron in stamp stems and did not make such a general statement as the above. Yours faithfully, T. A. Rickard.

Salmon City, Idaho, March 26, 1895.

Kingsley endorsed tobacco as follows: "It is a lone man's companion, a bachelor's friend, a hungry man's food, a sad man's cordial, a wakeful man's sleep, and a chilly man's fire." Kingsley himself was a great smoker, and he derived much comfort from the use of his clay pipe.

The Largest Piece of Gold Yet Found Was Worth Nearly $150,000.

To the Editor:—The largest piece of gold, free of quartz, in the world, was taken from the Byer & Haltman gold mining claim, Hill End, New South Wales, Australia, on May 10, 1872, its weight being 640 pounds, height four feet nine inches, width three feet two inches, average thickness four inches, and was worth $148,800. It was found imbedded in a thick wall of blue slate, at a depth of 250 feet from the surface. The owners of the mine were living on charity when they found it.

The Welcome Stranger nugget was found on Mount Moliagel, February 9, 1869; it weighed 190 pounds and was valued at $45,000. It was raffled for $46,000.

The Welcome nugget was found at Bakery Hill, June 9, 1859; it weighed 184 pounds 9 ounces 16 pennyweights, and was worth $44,356. It was raffled for $50,000.

The Lady Hotham nugget was found in New South Wales, Canadian gulley, September 8, 1854; it weighed 98 pounds 10 ounces 12 pennyweights, and was sold for $23,557.

The Union Jack nugget was found February 28, 1857; it weighed 23 pounds 5 ounces, and was sold for $5620.

No name nugget was found at Eureka, Dauttons Flat, February 7, 1874, at a depth of thirty feet from the surface; it weighed 52 pounds 1 ounce, and was sold for $12,500.

The Leg of Mutton nugget was found at Ballarat, January 31, 1853, at a depth of 65 feet; it weighed 134 pounds 11 ounces, and was sold at the bank for $32,380. This nugget was shaped like a leg of mutton, hence its name.

No name nugget was found at Bakery Hill, Ballarat, March 6, 1855, near the surface; it weighed 47 pounds 7 ounces, and was sold for $11,420.

No name nugget was found in Canadian gulley, Ballarat, January 22, 1853, near the surface;. it weighed 84 pounds 3 ounces 15 pennyweights, and was sold for $20,235.

The Kohinoor nugget was found at Ballarat, July 27, 1860, at a depth of 160 feet; it weighed 69 pounds, and was sold for $16,680.

The Sir Dominic Daly nugget was found February 27, 1862; it weighed 26 pounds, and was sold for $6240.

No name nugget was found at Ballarat, February 28, 1855; it weighed 30 pounds 11 ounces 2 pennyweights, and was sold for $7395.

No name nugget was found August 1, 1879; it weighed 12 pounds, and was worth $2280.

No name nugget was found at Ballarat, February 3, 1853; it weighed 30 pounds, and was sold for $7360.

No name nugget was found in Canadian gulley, January 20, 1853; it weighed 93 pounds 1 ounce 11 pennyweights, and was sold for $22,350.

No name nugget was found at Bakery Hill, March 6, 1855; it weighed 40 pounds, and was worth $9600.

The Nil Desperandum nugget was found November 29, 1859; it weighed 45 pounds, and was sold for $10,800.

The Oats & Delson nugget was found at Donolly gold field in 1880, at the roots of a tree; it weighed 189 pounds, and was sold for $50,000.

In addition to the above are the Huron nugget, worth $20,000, and the Empress nugget, worth $27,661. A great number of smaller nuggets, too numerous to mention, have been found.

Many large nuggets or lumps of gold have been found in California during the era of placer mining; but Australia must claim the largest. The California lumps are as follows:

A piece of gold and quartz was found in Calaveras county on Carson Hill, on the mother lode; it was valued at $42,000.

The Downieville lump of quartz and gold, of Sierra county, as stated by Louis Blanding, gave a value of nearly $90,000; but it was not a nugget.

The mass of gold and quartz found in the Bonanza mine, Sonora, Tuolumne county, gave a value of over $40,000.

The Australian statistics are correct, I having obtained them from Government authority. Argus.

Sonora, Cal., March 30th, '95.

The *Iron Age* says within the next six months there will be in operation in this country a total of 196 tin-plate factories, having a possible annual output of 6,350,450 boxes, which is more than the ordinary yearly consumption of the United States. Of these, 157 mills are either built or are in process of construction, and the arrangements have been made to erect within the next six months thirty-nine additional mills.

The illustrated article on the Standard Mining Co.'s plant at Bodie is completed in this issue. Fig. 5 shows that the power is furnished by Pelton wheels, as it appeared in the report of the State Mineralogist, which we were unable to reproduce, and the regulation is effected by the Pelton differential governor.

Mr. W. F. C. Hasson, of this city, has been elected one of the three vice-presidents of the American Institute of Electrical Engineers.

Some Practical Points.

To the Editor:—Getting drills to do work in hard rock may be a simple matter to the experienced mine smith, but to some of us amateurs who have to dress our own tools it is a problem which calls for some consideration. It is with the hope that some of the latter may be benefited that the following suggestions, derived by hard experience and later by some valuable hints from a veteran mine smith, are submitted:

First of all secure good steel, if possible; poor steel is especially dear in hard rock. Do not attempt to sharpen in the sunlight, and carefully avoid overheating the steel as it will often get burned slightly when hardly suspected. As most beginners have better success making a new bit than keeping it in shape, the following applies to the drill dulled by use: Lay the drill upon the anvil corner up and strike the first blows a little diagonally on the corners, which will narrow the bit and have a tendency to bring the steel on the corners out even with the middle to compensate for the wear which is greatest at the corners; also smooth down any irregularities at this time. Never begin on the flat side of the drill. Next turn the drill flat and again strike on the corners a few drawing blows, accompanied by necessary blows in the middle, to make the bit square across the edge; repeat this operation from each side until the bit is in shape, and on the round part of the anvil draw the steel down just back of the edge, to give the drill clearance. Deliver the finishing blows squarely against the level at whatever angle it is desired to maintain, until a sharp edge is secured; again see that the bit will clear itself, and with a few soothing taps on the edge it is done. The amount that the bit should be narrowed depends upon its dullness. A good bit will be nearly if not quite straight across the edge and will have a straight taper on the bevel, which will leave the flattened steel also on a nearly straight line. The steel should not be flattened to less than one-half its size. For ordinary hard granite an angle of 60° gives a good edge; for softer rock increase the cutting capacity by increasing the length of the bevel and not by flattening the steel. Avoid curves, and build the bit as close to the body of the steel as possible.

Allow the drills to cool somewhat, and if using an open fire, place a bar of iron across on which to lay the drills, to prevent the steel from getting heated back of the bit. When a uniformly dark red color is apparent in the shade, plunge the drill into tepid water and let it remain until cool, when, if properly tempered, it will present a speckled appearance. Conditions of light, grades of steel and rock vary, so that a little experience will be the best guide as to the heat required; but drills tempered in this way will not check nor "jump" a bit, and if too hard they will break clean. Geo. F. Willis.

Bishop, Cal., March 20th, '95.

The Good Old Times in Iron Manufacture.

In discussing Mr. John Fritz's recent paper on the "Early Days of the Iron Manufacture," read at the Bridgeport meeting of the American Institute of Mining Engineers, Mr. E. C. Pecbin said:

"For many years Mr. Hughes Oliphant operated a small charcoal furnace and mill at what is now Fairchance, in Fayette county, Pa., at the foot of the Alleghany mountains.

"He told me that early in the century he ran for eighteen months, and saw only $10 in money. I said to him: 'How under heaven did you manage?' He replied: 'We made our iron into nails, rods and kettles, hauled them twelve miles over to Brownsville, on the Monongahela river, loaded them into flat boats, and floated them down the Ohio, swapping our wares for whisky and rum. At New Orleans we exchanged these for sugar and molasses, which we sent by sea to Baltimore, and there we swapped again for groceries and dry goods, which we hauled in Conestoga wagons over the mountains, 300 miles, to our furnace.'"

Book Received.

"*Taxation of Personal Property.*" The author is Thos. G. Shearman, the well-known writer on economic subjects. He argues that the taxation of personal property is "impracticable, unequal and unjust;" he holds that the single tax, that is the tax on land, is the only right solution of the question he raises, and that manufactures, commerce and industry in every form should be released from taxation. As a starter he advocates local option—that is, to have each city or county or district decide for itself whether personal property in those limits should or should not be taxed. He argues well; his arguments, however, have all the attractiveness of theory, unaccompanied by the value that can only attach to tried and proved propositions. The price of the book is thirty cents: it is published by the Sterling Publishing Co., 106 Fulton St., New York.

Labor statistics for 1894 show that in the United States there were twelve per cent, or one-eighth, fewer hands employed than in 1892. That represents an unemployed army of 565,000 persons. In wages earned and not paid it stands for $500,000,000. Applied to product values it shows a falling off of $1,254,000,000 as compared with the year in which the people voted for a change.

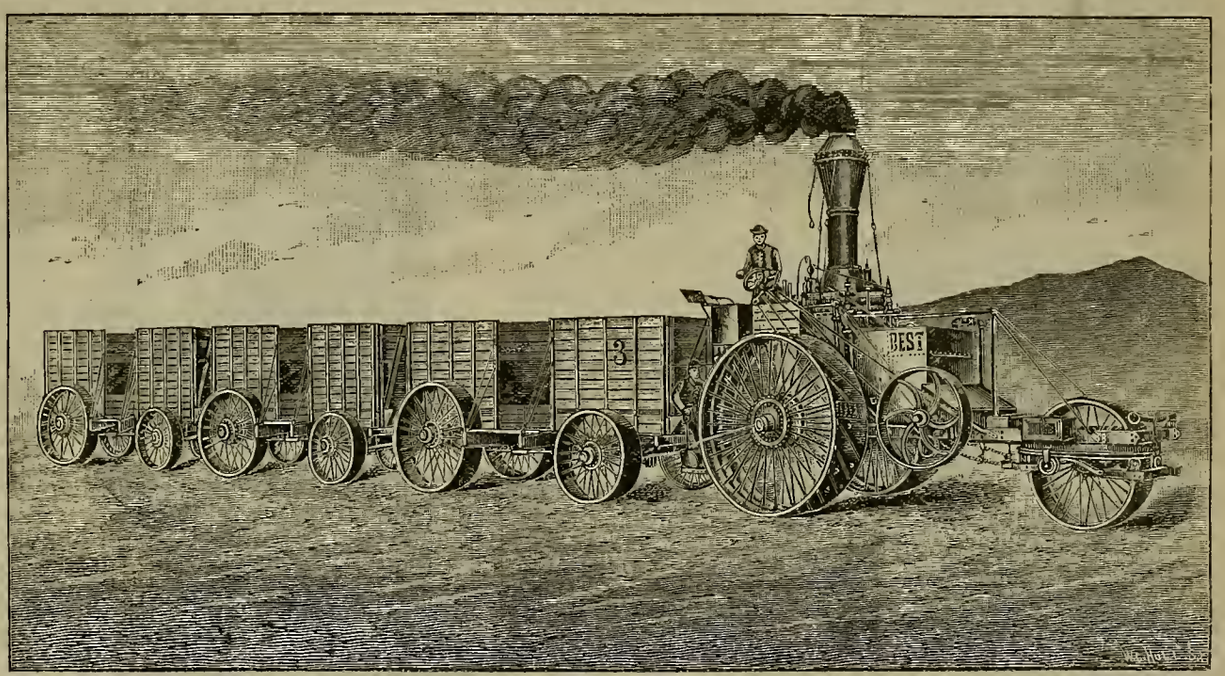
MANUFACTURED BY



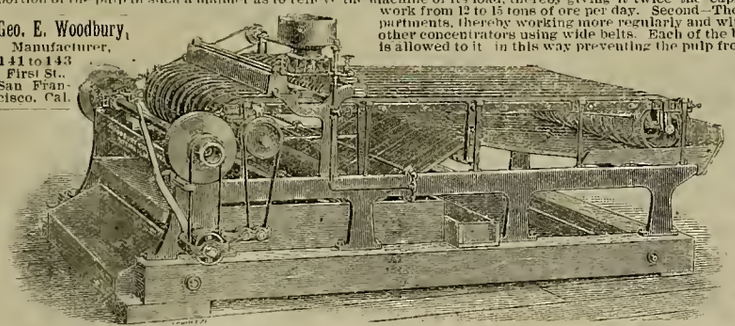
THE BEST MANUFACTURING CO., SAN LEANDRO, CAL., U. S A.

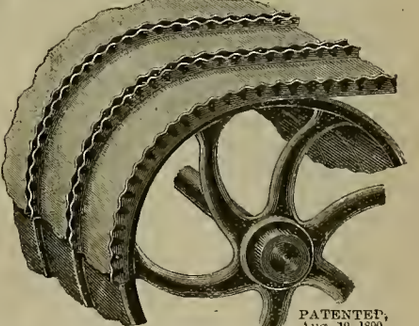
THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. **Price $575 f. o. b.** Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The Improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allowed to it in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury, Manufacturer, 141 to 143 First St., San Francisco, Cal.





PATENTED, Aug. 19, 1890.

This Concentrator took the 1st prize at the San Francisco Mechanics' Institute in 1890, 1891 and 1892, and at the California State Fair in 1892; it took the 1st prize at the World's Columbian Exposition, 1893, and at the San Francisco Midwinter Fair, 1894.

Scientific Progress.

Theory of Professor Wellner's Flying Machine.

The essence of Professor Wellner's innovation is his invention of the sail wheel. It consists of a horizontally placed axis with spokes and arched aeroplanes attached to them in a cylindrical form. While revolving round the axis the latter take a slightly slanting position, which causes the forward edges of these surfaces to be inclined, and consequently to compress the air in the way of a sail or a kite, calling into play the vertical force. These ribs, running across each lifting surface and made in the form of a screw, at the same time serve to strengthen the aeroplanes and to add to the horizontal force.

These sail wheels, set in pairs, can be placed, according to the size of airship aimed at, in one or more groups of two wheels, revolving in opposite directions, behind or beside each other. The cigar-shaped car, furnished with a motor and carrying the aeronants, is attached horizontally under the center of the wheels, so that the whole construction will resemble a colossal bird, propelled, instead of by wings, by revolving wheels, the lifting surfaces of which are consecutively and constantly developing vertical and horizontal power. The bird's movements in flying and the speedy headway motion necessary to the kite-flying machines for their support in the air are in Prof. Wellner's invention changed to a rotary motion. This construction, while permitting of an easy, slow ascent, assures the horizontal position and constant stability of the airship, at the same time permitting of a high velocity.

The more the latter is increased the stronger is the lifting power developed. The direction is given by a rudder at the end of the ship or by increasing the velocity of the sail wheels on one side only. It is the peculiar quality of these wheels that they do not, as might be supposed, disperse the air around them. They rather attract it toward their rapidly moving surface, condensing it to a powerful stream, which passes down obliquely through their cylinders. Their velocity can be made to surpass by far that of railway trains, thus enabling them to conquer contrary winds and air currents.

Iron Older Than History.

Iron was used before history was written. The stone records of Egypt and the brick books of Nineveh mention it. Genesis (ix., 22) refers to Tubal Cain as "an instructor of every artificer in brass and iron," and in Deuteronomy (iii., 11) the bedstead of the giant Og was "a bedstead of iron." The galleys of Tyre and Sidon traded in this metal; Chinese records ascribed to 2000 B. C. refer to it; Homer speaks of it as superior to bronze. The bronze age came before the iron age, because copper, found as a nearly pure metal, easily fuses, and with another soft metal—tin or zinc—alloys into hard bronze; while iron, found only as an ore, must have the impurities burnt or hammered out by great heat and force before it can be made into a tool. The word sometimes translated "steel" in our English Bible really means bronze or brass, but steel was distinctively known to the later ancients. Pliny the Elder wrote in the first century of our era: "Howbeit as many kinds of iron as there be, none shall match in goodness the steel that comes from the Seres (Chinese), for this commodity also, as hard ware as it is, they send and sell with their soft silks and fine furs. In a second degree of goodness is the Parthian iron." Asia probably made more iron and steel thirty centuries ago than it does to-day. About the time of the first Olympaid, 779 B. C., there is authentic record of the use of iron in Greece, and Lycurgus used it for the money of Sparta. Iron and steel weapons of war began to displace those of bronze before the battle of Marathon. The Romans learned iron making from the Greeks and the Etruscans, their mysterious and highly civilized neighbors, and obtained iron largely from Corsica, where the mines had been worked from prehistoric period. The Roman legionaries found in Spain steel weapons of the finest temper, and Diodorus says that the weapons of the Celtiberians were so keen "that there is no helmet or shield which cannot be cut through by them." Toletum (now Toledo) was then as famous for its sword blades as afterward in the middle ages. Cæzar found the painted Brittons fighting with spearheads of bronze, but wearing armlets of iron, and remains of pre-Roman forges are still found in England and Wales. The Germans knew the art of sword forging, and their legions of dwarfs and trolls with magic swords point to an earlier people, adepts in mining and metallurgy.

Ink Eraser.

Please inform me how to make a solution that will erase ink and ink blots without leaving any trace on the paper.

1. Tin chloride, two parts; water, four parts. To be applied with a soft brush, after which the paper must be passed through cold water. 2. Thick blotting paper is soaked in a concentrated solution of oxalic acid and dried. Laid immediately on a blot, it takes it out without leaving a trace behind. 3. The "Journal de Pharmacie d'Anvers" recommends pyrophosphate of soda for the removal of ink-stains. This salt does not injure vegetable fiber, and yields colorless compounds with the ferric oxide of ink. It is best to first apply tallow to the ink spot, then wash it in a solution of pyrophosphate until both tallow and ink have disappeared.

JUPITER takes eleven years and ten months in making his journey around the sun. Thus, our earth travels nearly twelve times around the sun while Jupiter goes around only once. This is easily explained, since Jupiter is five times farther from the sun than our earth, and therefore has a greater distance to travel. For the same reason, Jupiter receives much less light and heat from the sun than we do. In each second of time Jupiter's giant bulk moves eight miles, a rate which is about five hundred times faster than the swiftest express train.

AN ink for writing on glass is prepared as follows: Dissolve 36 parts of fluoride of sodium in 500 parts of water and add 7 parts of sulphate of calcium. Prepare a second solution by dissolving 14 parts chloride of zinc in 500 parts of distilled water and add 65 parts of strong hydrochloric acid. For use, equal parts of these two solutions are mixed together and diluted a little, or mixed with some ordinary ink in order to make it flow better. Very fine writing and drawing may be done with this ink.

THERE are now fifty-four so-called metals whose physical properties are well known, and there are fifteen others whose properties are being investigated. These latter materials are the recently discovered idunium, davyum, mosandrum, holmium, samarium, norwegium, veshium, neptunium, lavoisium, uralium, harcenium, colshim, rogerium, comesium and actinium.

A RECENTLY patented composition of metal consists of twenty-four ounces of tin, twelve ounces of zinc, and one pennyweight of aluminum. It is used as an imitation of silver in white metal goods.

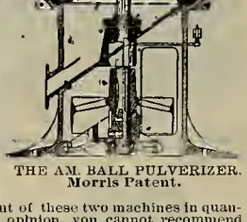
Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O., Jan. 25, 1894.

The American Mining & Milling Machinery Co., Cleveland, O.:

GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now call per 4¾ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows LESS; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with LESS than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,

CLEVELAND IRON ORE PAINT CO.



THE AM. BALL PULVERIZER. Morris Patent.

Mechanical Progress.

The Straining of Boilers.

There are few things more annoying to a steam user who has just put down new modern steam boilers than to find them exhibiting signs of straining and leakage in a few weeks, or mayhap in a few days, after being put to work. Possibly no expense has been spared in the equipment of the boilers, to have them up to date and in accordance with the most approved practice; but, notwithstanding all the precautions taken, straining occurs, and often shows itself by leakages at the rivets securing the gusset stays to the front end plate. Although less likely to have serious consequences than concealed leakages, they are none the less aggravating because visible to all and sundry who may be brought to look at and admire the new boilers, which it was fondly hoped were the best that money could buy. However unpleasant this experience may be, it is that of many firms who, in order to keep pace with the times and meet competition by cheapening production, have tripled or quadrupled their engines, and replaced boilers working at moderate pressures by new steel ones suitable for 150 to 200 pounds working pressure.

It is interesting to trace a few of the causes of this straining in new boilers, and to point out how they may be avoided. One of the most frequent, perhaps, is that of making the end plate too rigid, either by having it too thick or too rigidly confined by the end stays, thus preventing the plate from slightly buckling, or "breathing," in sympathy with the elongation and shortening of the flue tubes, constantly occurring with variations in temperature.

Another prolific cause of straining is the overheating of the plates, resulting from the use of impure feed water. When the water is impregnated with mineral matter, in the form of carbonate and sulpbate of lime and magnesia, etc., unless means are taken to prevent it, the lime salts are precipitated and deposited on the heating surfaces as scale, preventing contact of the water with the plates, and overheating and unequal expansion ensue, in addition to more or less waste of fuel. The overheating from this cause is increased when carbonate of iron is present in sueb quantity as to thicken the water and retard steam bubbles in their passage to the surface of the water.

Another and more serious source of mischief is the presence of oil in the boiler, admitted with the feed water when taken from the hot well of a jet condensing engine, or heated by direct contact with steam from the cylinders. This, especially where the water contains carbonate of lime, is responsible for a great deal of the trouble arising from straining. The oil, which may have been carried into the boiler in a free state, or in finely divided particles intimately mixed with the feed water, is left behind on the latter being evaporated, and accumulates until in sufficient quantity to combine with the particles of lime in the water. This settles in the form of globules on the crowns and upper sides of the furnaces, effectually keeping the water from direct contact with the metal, thus interposing a barrier to the free transference of the heat of combustion to the water, with the result that the temperature of the plates is increased to such an extent as to produce severe straining at the seams and end plates, even if actual distortion or collapse does not take place.

One other cause should be referred to, as it is of very common occurrence, especially in small plants, viz., feeding the boilers with cold, or comparatively cold, water. In modern plants, consisting of one or more large boilers, it is usual to pass the feed water through an economizer or heater placed in the main flue, by which means it is raised to a very high temperature by utilizing a portion of the heat from the waste gases, which would otherwise be lost up the chimney. There are, however, hundreds of new boilers put in, to say nothing of the thousands of old boilers, which are fed with water only slightly heated, or even at the temperature at which it is obtained from the main reservoir or well. Did the owners but realize that by the one fact of using cold feed water they were not only wasting between 10% and 18% of fuel, according to the temperature of the feed water and the steam, but also shortening the lives of their boilers by years, besides running the risk of heavy expenditures for maintenance, they would at once take measures to obviate such a wrong state of affairs. If inconvenient to put down an economizer, the water could readily be heated by means of an exhaust or live steam heater, or by an injector, to the great advantage of the owner.

We have seen that there are four chief causes for the straining of boilers, viz: End plates too thick or too rigidly stayed, impure feed water, presence of oil in the boilers, and the use of cold feed water. The first cause can very often be removed by dispensing with the bottom rivets securing gusset stays to the end plates. Impure feed water can generally be purified by suitable treatment before going to the boiler, by a chemical process and filtration; or, if the first cost of the plant necessary is too great, or space is very limited, by introducing suitable reagents adapted to treat the impurities found by analysis to be present in the water. By the latter method the lime salts, etc., are rapidly precipitated, and rendered easily removable by blowing out, in addition to gradually softening existing incrustation. If mineral oil of good quality be used in the cylinders only in such quantities as are really required for lubrication, there is no serious danger to be apprehended from the small proportion reaching the boiler with the feed water, unless there be carbonate of lime present in considerable quantity, in which case oil should not be admitted under any circumstances whatever. Good results have accrued in many instances from fixing an oil and water separator on the feed pipe, between the pump and boiler, to intercept any free oil which may be present in the water.—Practical Engineer.

Arrangement of Machinery in Power Stations.

Three general methods of arranging machinery of power stations are common in the United States. In one the power is transmitted from the prime mover to a line shaft, and thence, by belting, to the dynamos. This we will call the line-shaft system. In another the power is transmitted by a belt or rope from the prime mover directly to the dynamo. This we will term the direct-belted system. In the third the shaft of the dynamo or generator is directly connected to the prime mover, and has the same speed of rotation. This we call the direct-connected system. Regarding these several systems, it may be said that local conditions or surroundings may be such as to render it advisable to adopt one or the other. The writer, however, believes that it will be seldom or never necessary under present conditions of manufacture to adopt or use the line-shaft system. That system is objectionable for various reasons.

The direct-belted system is to-day the cheapest in first cost and in many respects the most satisfactory to operate. The arrangement of the generators, distinct from the prime movers and connected by flexible connections, makes it possible to repair accidents with great facility and convenience. In general, with this system, only one or at most two generators can be driven from an engine without the use of riding belts. With the condition of the market as at present, however, with generators available of any size required, this matter is of little practical importance.

The direct-connected system is without doubt the ideal system, since transmission losses are eliminated and the power occupies a minimum amount of space. The cost to-day would be about twenty per cent in excess of the direct-belted, but not essentially greater and possibly even less than that of a well-constructed line-shaft system. The American practice in building direct-connected machines is to extend the main shaft of the engine and suspend the generator armature on the end, either with or without an out-board bearing. The English system is somewhat less rigid, the engine shaft being connected to the dynamo with a coupling.—Prof. R. C. Carpenter in Cassier's Magazine for April.

Professional Cards.

A. H. RICKETTS, Attorney-at-Law,
Mining Patents and matters before the Land Department a Specialty.
Crocker Building, Rooms 201, 202 and 203, San Francisco.

The Evans Assay Office.
W. N. JEHU, - - - - Proprietor.
Successor to Jehu & Ogden.
628 Montgomery Street, San Francisco.
Rooms 46 and 47 Montgomery Block.
Ore Assays, Analyses of Minerals, Metals and their Alloys, Etc.
LESSONS GIVEN IN ASSAYING.

School of Practical, Civil, Mechanical,
Electrical and Mining Engineering.
Surveying, Architecture, Drawing and Assaying.
723 Market St., San Francisco, Cal.
OPEN ALL YEAR.
A. VAN DER NAILLEN, President.

Assaying of Ores, $25; Bullion and Chlorination Assay, $25; Blowpipe Assay, $10. Full Course of Assaying, $50. Established 1864.
Send for Circular.

JOHN W. GRAY, Engineer and Surveyor.
Examination, Surveys, and Reports upon Mines, Drainage, Tunnels, etc.
Development of water for mining and domestic use, irrigation, and the production of power. General Surveying of all kinds, and plans prepared. Construction work superintended. Correspondence solicited.
Res.—923 Linden St., Oakland, Cal.

EDWARD S. COBB,
Mechanical Engineer and Expert.
Tests and Estimates for the improvement of Pumping, Power and Hydraulic Plants.
Will supervise the Construction, Shipment or Erection of Machinery. Will make Drawings, Estimates or Specifications.
Prices obtained for machinery of every description. Twenty year's experience.
23 Davis St., Rooms 30 & 31, S. F., Cal.

GILES OTIS PEARCE,
Mineralogist and Metallurgist.
708 Colorado Avenue, Colorado City, Colo.
Will examine Mines, Ore Bodies, Mineral Belts or Zones, and make written Mineralist Reports, fees for which made known upon application for services. I make my own assays and select my own samples when examing mines. Eighteen years' experience. Analysis of water and soils.

Almarin B. Paul, M. E.,
Mining Operator,
ROOM 5, CROCKER BUILDING,
Cor. Market and Montgomery Sts., San Francisco.
Will give attention to the sale of and reporting on RELIABLE Mining Properties, or the procuring of suitable Machinery for Interest in Developed Mines.
Plans and Estimates made for IMPROVED CYANIDE PROCESS PLANTS, and competent instruction for working the same on a large, practical scale.

Nevada Metallurgical Works,
No. 23 Stevenson Street,
Near First and Market Sts., San Francisco.
C. A. LUCKHARDT, Manager.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MINING ITEMS—BELL WETHER.—*Republican:* By the terms of the verbal agreement between S. W. Bright and Jos. Underwood and Dr. Snedeker, of Chicago, for the disposal of this property, the latter are to commence work on or before the first day of May. From the commencement of work until the mill is erected and in running order, Mr. Bright is to receive $300 per month. After the mill is in operation, 20% of the gross proceeds is to be paid to the owner until the full amount is paid, which we understand is $110,000. The purchasers are required not only to commence work at the above time, but to prosecute development work, and the erection of a mill to completion as soon as possible.

ALMA.—At this mine the shaft has reached a depth of 390 feet. At the depth of 400 feet it is intended to drift for the ledge, which it is believed will be tapped withiu 100 feet of the shaft. While drifting is in progress, sinking will be continued—at any rate, to the extent of providing a sump to hold the water. A month or six weeks ought to suffice to reach the ledge, unless its departure from the usual dip of the mother lode toward the east is much greater than is supposed. On the surface, especially where, as in this instance, the country is considerably broken up by upheavals of the earth's crust, the extent to which this has affected the pitch of the ledge near the surface is always more or less problematical.

Robert Aitken has sold his interest in the Clyde quartz claim to the Kennedy Mining Company, for $1500. The Clyde joins the Kennedy on the east.

The mill of the Smith brothers, on the Clough place, near Volcano, has come to a standstill. The reason for the stoppage is not known. It has been reported that the parties were more than satisfied with the yield of the rock so far, and that there was no doubt that the sale of the property would be completed. The shutting down of the mill following the circulation of these cheering reports is inexplicable.

NEAR VOLCANO.—Adams & Hanley have a vein of ribbon rock on the Hanley claim, near Volcano, which, it is though, will mill $150.

THE HANCOCK, MIDDLE BAR DISTRICT.—The company which is prospecting the Hancock mine has driven its tunnel in southward in the footwall of the ledge aud is in a little over 200 feet and still pushing forward. Harry Summers has charge of the work.

THE ALMA, JACKSON DISTRICT.—In order to enable them to make some kind of estimate as to the timber to order this summer, and incidentally to ascertain the pitch of the ledge and its value, the Alma people suspended sinking a few days ago and are now eugaged in crosscutting to the ledge from the 400 level. As soon as the ledge is encountered, and its width, pitch and assay value ascertained, they propose to continue sinking.

Butte.

AROUND BANGOR.—The Catskill has forty men at work and the gravel has paid regularly since the new company began operations. The owners of the Turner mine have struck excellent gravel and will soon be taking out gold. Two young men, Peter Berdell and Henry Devol, while out prospecting for quartz struck a pocket of quartz gold and took out $800 in five hours work.

ON HOLTE'S FLAT.—The Holte Mining Company is developing a gravel mine on Holte's Flat. Supt. Burroughs has a crew of men engaged in running a cut from the flat to the river. He expects in a short time to strike bedrock and then will commence drifting.

AROUND MAGALIA.—At the Alki mine several men are employed: Supt. Geo. Parry will soon be taking out gold.

The incline on the Aurora mine is down 190 feet. There is but little water in the bottom and the surface water does not occassion much trouble. About ten men are at work and they will reach the face of the old workings about the first of May.

In the big Magalia mine matters are assuming shape for renewed sinking of the great shaft. A big Dow pump, weighing 14,000 pounds, or about three times as much as the ordinary mining pump, is being built in San Francisco and will soon be completed. A gigantic compressor is in place and is run by water power. The air compressor is a compound one and exerts immense power. This will be used for pumping. The hoist will be run by water power. There is now about 100 feet of water in the shaft, but this will soon be pumped out and work resumed in sinking the shaft. The air compressor is capable of exerting a force equal to 300-horse power, while double this power can be developed in case of necessity.

Calaveras.

BOSTON MINE.—*Chronicle:* The water-power hoist is in running order and of sufficient capacity to sink the shaft 500 feet. The two-compartment shaft has reached a depth of 50 feet. The winze inside of the main tunnel has been suuk 45 feet and a crosscut made to the footwall of 19 feet in very rich quartz heavily charged with galena sulphurets. A milling test of the winze ore gave $65 in gold aud 7 ounces in silver. Five hundred feet to the south of the shaft the lead has been cut across with an open cut and the vein was found to be 35 feet wide and giving an average assay of $7.53. This part of the lode will furnish quartz for a twenty-stamp mill for the next ten years at a large profit, for the quartz can be broken and milled for $1 per ton. No hoisting of ore need be done, as there are 225 feet of backs above the tunnel level. Seventeen men are at work preparing the mine for cheap and economical working when the twenty-stamp mill shall have been put in for crushing ore, which will probably be during the next ninety days.

El Dorado.

THE TOCKEY MINE.—The ten-stamp mill at the Tockey mine is nearing completion.

Inyo.

NEAR INDIAN WELLS.—J. Lee and F. Meysan are reported to have discovered the biggest gold ledge and property ever found in the county, near Indian Wells. Some rich samples are shown in Keeler. About ten claims have been located and all the available ground has been taked up. No flattering reports have been received only from the first location, which may only be a small rich pocket.

Mendocino.

A PROBABLE FIND.—Mendocino produces other things than lumber. Miners with primitive appliances years ago made as much as $3 a day out of the gravel in Gold gulch, some few miles north of Ukiah, at times in a rainy season, when there was plenty of water available, and now a gold-bearing quartz ledge is reported discovered on the south fork of Big river.

Nevada.

A PROBABLE PURCHASE.—Louis Janin has been looking at the Boss mine on the San Juan ridge, and it is thought Jas. D. Hague will shortly buy it.

AN ASSESSMENT.—An assessment of five cents per share has been levied by the Gold Point Consolidated Gold and Silver Mining Company.

GETTING READY.—*Transcript:* W. F. Englebright is engaged in surveying the exterior and interior boundaries of the Mayflower quartz mine, at Cauada Hill, and will make a map of the property for the company.

AT MEADOW LAKE.—*Republican:* Salt Lake men are honding mines in Meadow Lake district. It is understood that the Salt Lakers have discovered a process by means of which the ores of the district can be profitably worked. About the only base metal in the ore is iron. The great trouble is a superabuudance of iron. Most of the lodes may be described as veins of iron ore containing gold. In the early days when these mines were first discovered a great deal of gold was obtained by sluiciug, panning and sacking the decomposed croppings of the veins, but at depth, where the iron was bright and solid, no milling process would get the gold. I have always believed, says Dan De Quille, that the cheapest way to work the ore would be to crush it, run it out upon a patio, salt it down and leave it till thoroughly oxidized and decomposed, when it would be an easy matter to wash out the gold.

THE HARMONY.—*Herald:* In the Harmony gravel mines at Nevada City a drift is now being run across the channel. It is now in 120 feet, and the gravel is still good. As soon as the mine is opened so that men may be worked to advantage, a large force will be put on.

WASHINGTON DISTRICT.

GETTING READY.—*Herald:* Supt. Fisk is prepariug for the summer's work on the Ogdensburg and St. Lawrence gravel mines at the headwaters of Fall creek. On account of the deep snow all operations were suspended, but as soon as possible the development work will be continued. Excellent prospects have been obtained so far and all the indications are towards improvement.

Orange.

REOPENING THE BLUE LIGHT.—Orange *News:* The Blue Light mine, in the Silverado canyon, is being reopened. The trail to the mine has been cleared and widened, and Mr. Dunlap has just returned from San Francisco, where he purchased all the machinery necessary to break, pulverize and cocentrate the ore. A ditch is being constructed along the north side of the canyon, where, in a distance of half a mile, over 124 feet fall can be obtained. The water will be utilized as power and will operate the machinery by means of a Pelton water-wheel. The ore contains both gold and silver in paying quantities.

Placer.

MINE BONDED.—*Herald:* Bell, Seaver & Wyman have bouded their rich claim at New England Mills to Messrs. Col. Wallace, B. F. Hartley, G. E. Evans and M. T. Lawrence. The figure is said to be a large one.

MINING NOTES.—*Sentinel:* Preparations are being made at the Alta mine to draw the water from the old works before connection is made through the new tunnel. It is expected to tap the old mine some time during the coming summer.

W. Gray is running an upraise in his mine, the Rough and Ready, at Dutch Flat, and soon expects to tap gravel.

Phil Bailey and John Uren have begun work in the Oak and Cedar mine, just below Dutch Flat. They will drive the bedrock tunnel ahead and hope to strike the channel in about fifty feet. The tunnel is in about 500 feet already.

Everything is in readiness at the Golden Shaft to erect the mill recently purchased, with the exception of the timbers, which will have to be brought from below, as it will be too late to wait for the mills to start up. Owing to the excellent quality of gravel found in this mine, its future is awaited with much interest. If it proves a success it will doubtless stimulate prospecting very much in the vicinity of Dutch Flat and Gold Run.

Plumas.

THE BUTTERFLY MINE.—*National-Bulletin:* In consequence of a lack of power only five stamps of the mill of the Butterfly mine are running.

AROUND LAPORTE.—The Pioneer mine has an increased number of men and is paying handsomely. The Cleghorn is preparing for considerable work this season. Packer & Hendle are about to work several miles of the bed of Slate creek.

THE THISTLE MINE.—Nearly 100 men are now employed in and about the Thistle mine, which is considered to be the richest drift mine in northern California.

Riverside.

AROUND PERRIS.—At the Good Hope mine fifty-three men are now employed; the output is about fifty tons of ore daily. The Santa Rosa, six miles distant, has a 320-feet shaft and about 1440 feet of drifts. A ten stamp mill daily handles twenty-five tons of $20 ore. Thirty-two men are employed. The Santa Fe is close to the Santa Rosa and is being reworked by Supt. Stover with good indications... There are about forty claims in the vicinity in which considerable developing work is now being done.

San Bernardino.

VANDERBILT DISTRICT.

Montgomery is still pushing ahead, and will in all probability make a lasting camp. There is not only one good mine there, but several. A large portion of the ore is of very rich character, running as high as $500 to the ton in gold, and is also very free milling. There are at the present time twenty-five tons of machinery on the road for this camp, and two six-horse teams have been busy for some time past hauling provisions alone from Vanderbilt. There are forty men employed, with a likelihood of several more being put on in the course of two or three weeks. Montgomery is about 120 miles from Vanderbilt.

Gus Williams and Pete Wagner are having ten tons of Shadow mountain ore milled at Campbell's mill.

Several of the men who worked for Gaselle at the Shadow Mountain mines have placed an attachment on the property for two months' pay. It is reported that there is plenty of good ore in sight, enough to more than pay off the indebtedness, providing the mill can save a large proportion of the gold.

IN HOLCOMB VALLEY.—The Holcomb Co., an English company, is working twenty-five men on their placer property, using a steam shovel and revolving screen amalgamator, the six feet gravel bed going from forty cents to $1.00 per yard. Considerable money has been spent on this property and present indications favor satisfactory returns.

San Diego.

RICE DISTRICT.

At this new district, near Warner's ranch, the Daisy and Bertha shows a three foot vein of $20 ore. A 350-feet tunnel is being run. The Morning Star and Yellow Hammer are being developed, each showing a four-feet vein of pay ore. A fine stamp custom mill will be built this season.

BANNER DISTRICT.

Fifteen dollar rock is being produced at the Ready Relief and Redwood mines. In the Hubbard, adjoining, a tunnel 100 feet below the old works is being run to the ledge.

Shasta.

A SAMPLE OF MANY.—Free *Press:* H. Cochran, a prosperous miner of French Gulch, was here this week to file a mineral affidavit in the Land Office on the odd-numbered section on which his claim is located. He can offer ample proof that the land is mineral in character, for inside of one month he took out ore that netted him $1500 in cash. He crushed fifty tons which average $40 to the ton.

A LUCKY FIND.—Redding *Free Press:* Recently one Taylor, who came up here to work for the sandstone company on Clear creek, was fortunate enough to find a piece of gold and quartz which weighed 52 ounces. Clear creek has been rich in placers, and this man had occasion to repair a fence where there was an old dump pile of tailings. On this dump, amid stones and gravel, lay this lump of gold aud quartz as big as your two fists. Of course he picked it up, and at once became richer by at least $600. No doubt this nugget had been deposited years before by some placer miner, who threw it away, covered with mud, with stones from his longtom. The man who had earned it by his labor did not get it, but a stranger instead.

A few weeks ago, near Delta, a miner, in clearing away a place to erect an arrastra, picked up a lump of gold weighing $63. Gold will be found from time to time until the day of resurrection.

THE TELLURIUM. — *Free Press:* William Stevens has the contract to erect the works for the Tellurium Company, which he expects to finish about the middle of next month. The process for saving the gold, as introduced by A. F. Murdoff, and briefly explained by Stevens, is as follows: The ore will first go through the rock breaker, then into a drier; from the drier to the stamps at present in position, which will be used temporarily until a pulverizer is provided. The product will then be elevated to tanks containing a secret solution which is supposed to dissolve the gold. The gangue will next be run into a filter, through which the solution will be forced by means of steam, and will then be conducted to precipitating tanks, where, after the gold is precipitated, the solution will be elevated to the tanks first mentioned, to be used on the next batch of ore. By this process it is expected to make a profit on low-grade ore.

A RICH MINE.—*Free Press:* Ellery brothers, who own a mine at French Guleh, recently discovered and located, made a cleanup from a short run of about a week with a Huntington mill, and got 100 ounces of amalgam, or about $1600.

Sierra.

THE ALASKA MINE.—Grass Valley *Tidings:* It is reported that the mill at the Alaska mine had to be shut down, owing to the machinery being worn out. A new mill will probably have to be built, and it is thought an electric plant will be put in.

Sonoma.

DECLARING DIVIDENDS. — James Mead, a stockholder in the Great Eastern quicksilver mine, twelve miles from Healdshurg, reports that thirty men are at present employed in that mine, and healthy dividends are being declared.

NEVADA.

STOREY CO.

ON THE COMSTOCK.—The average of Con. Cal. & Virginia ore is rapidly rising. It is now up to $56.83 a tou. The Chollar people are shipping ore to the Nevada mill that averages $33.46 a ton. The Nevada mill is in Virginia City, and is run hy electricity. The Potosi is yielding ore that averages $48.53 a ton. The low-grade Savage ore, now being mined, averages $19.86. The Crown Point low-grade averages $9.86, $8.73 of which is gold. They extract about 650 tons a week. The ore of the Belcher goes $17.26 a ton. At the Alta they have found au eighteen-inch streak that averages $40. The ore of the Hale & Norcross averages $48.89. On the 500 level of the Occidental they now have ore that averages $41 a ton.

The following official reports have been placed on file in their respective offices:

BELCHER.—On the 300-foot level the joint Belcher and Seg. Belcher drift is in 112 feet from the shaft; the face shows porphyry and quartz of no value. They have hoisted during the week aud stowed in the ore dump at the mine 37 tons of ore of the average top-car samples assay value of $33.95 per ton.

CHALLENGE.—From the surface tunnel the joint Confidence and Challenge raise is up 37 feet; top shows quartz of no value.

SEG. BELCHER.—On the 200-foot level the main south drift is now 454 feet from the Belcher shaft; face in porphyry. Hoisted during the week and stored in the ore-house at the mine ten tons of ore, the average top-car samples of which show an average assay value of $33.15 per tou.

SAVAGE.—On the 950-foot level the south drift started from face of the sill floor, south-east drift, was advanced 18 feet; face is in low-grade ore. The east prospecting drift, started from the fifth floor of the ore stopes above the 1000 level, is advanced 36 feet. This drift has passed through 30 feet of low-grade quartz. They are repairing the main hoisting shaft from the 950 to the 850 level, and have hoisted no ore during the week. On March 29th they shipped to the United States Mint at Carson 232 lbs of bullion of the assay value of $5378; net coin value of the same $3276.

CROWN POINT.—In the Crown Point mine during the past week they continued to extract from the stopes between the 600 and 700 levels, and above the former the usual amount of ore, and have shipped to the Mexican mill 544 tons and 980 pounds of the same. The average battery sample was $11.24 per ton, of which $9.95 was gold. There is no particular change in the condition of the stopes except that above the 600-foot level the pay has narrowed and is practically exhausted, but as they follow north on the 600-foot level the width is maintained and the grade is from $7.50 to $10 per ton.

LINCOLN.

BIG ORE BODY.—The Salt Lake *Tribune* tells of a big find of valuable ore near the boundary line between Utah and Nevada, in Lincoln county. There is said to be more than an acre of surface croppings, which assay $5 to $6 in gold and $4 in silver. The property is located fifty miles west of Frisco, Utah, in a country that affords abundance of wood and water for mining purposes. The expert became so delighted with the property that he took a hond on it, the amount of which is understood to run considerably above $100,000.

ARIZONA.

TOMBSTONE DISTRICT.

GOLDEN QUEEN MINING CO.—The *Prospector* is in receipt of information, from undoubted authority, of the incorporation of a company of New Orleans capitalists to work a group of mines in Tombstone district.

The company is capitalized for $1,000,000, divided into $100,000 shares of a par value of $10 each. The sum of $50,000 has been paid in as a working capital. The name of the corporation is the Golden Queen Mining Co. The Plans have not all been perfected yet, but it can be positively stated that inside of thirty days work will be commenced on a large scale on some of the choicest virgin ground in this district.

BIG BUG.—*Courier:* There is daily expectation that the Pratt mill will be started up when the Bell, the Beleher, Hamilton and Poland will begin to take out ore.

LYNX CREEK.—The Howell or Morse mill on Lynx creek has been running on ore from a claim between the Pine Mountain and Shelton group.

THE HARQUA HALA.—*Times:* This gold-mining camp, located northeast of Yuma, in Yuma county, still remains one of the best camps on the Pacific coast as a bullion producer.

The number of men at work on the company's property is about 100, and there are 500 people in the camp.

Considerable prospecting and development work is going on in the district on private claims. The ore which is being run through the mill is from the Bonanza and Golden Eagle, the ore from the latter having to be hauled a couple of miles. According to the superintendent's reports the bullion output for the past year has been from $15,000 to $25,000 a month. Freight still goes in by way of Aztec, as the new railroad does not go near enough to the camp to lessen the distauce to haul.

Isaac Hester, with twenty head of horses, is

kept busy delivering freight to the mine, a distance of sixty-five miles.

BRITISH COLUMBIA.

AROUND THREE FORKS.—Soft weather and the inability of the Nakusp-Slocan railway to handle the output, has compelled the closing down of the Reco and Goodenough mines, and it is not improbable but that others will follow suit for the same reasons.

The ore blockade in the different warehouses and at the concentrator spur reminds one of the famous wheat blockade in the Palouse country a few years ago. Could transportation be had the product of this winter would have exceeded the estimates made last fall, which were placed at 10,000 tons. The railway people could not be made to believe this, however, and put 2500 tons as the quantity which would be shipped. From one mine, the Slocan Star, more than this entire amount has been furnished, and had no shipping facilities, Mr. White could have doubled his output.

The concentrator below town keeps grinding away on Almo and Idaho ore. Engineers have finished the surveys for tramway lines leading from the Idaho, Almo and Cumberland mines to the concentrator. The main tramway will be double tracked, 7000 feet in length. From it three others, from 1500 to 2000 feet in length, will lead to the different mines owned by the syndicate. A flume two by three feet and two miles in length will be built at once to convey an adequate supply of water from the south branch of Carpenter creek to the concentrator, as heretofore the entire works could not be operated on account of a scarcity of this necessary agent in concentrating.

Lack of funds to make the second payment has caused the holders of the bond on the Fisher Maiden and Silverton, on Four-Mile creek, to throw up the bond, although it is claimed the mines looked well. Fifty tons were shipped last fall, which ranged from 265 to 347 ounces silver per ton. This is dry ore, pure and simple, carrying no lead. The original owners have a fairly well developed property, quite a quantity of ore mined, and the first cash payment to console them for their disappointment.

Finch & Campbell have forfeited their bond on the Wonderful group, three miles from Three Forks.

COLORADO.

AROUND IDAHO SPRINGS.—Several mines which have been having ore treated at stamp mills have tried the system of concentration, and find more values are saved by this process. As soon as arrangements can be perfected with the milling people the ore will go to the concentrators for reduction. The mills recently started up are not working to their full capacity, as they prefer having the ore piled up than a scarcity on account of the early floods which may interfere with the hauling. Contracts are being made for future treatment and the indications are encouraging for an early rush. The mines located back in the mountains are piling up ore and also have immense bodies ready to be taken out. Considering the fact that the mills have been working all winter on ore convenient to the town it can be readily seen that every one of them will be taxed to its full capacity working twenty-four hours each day and seven days each week. Yet all of these will not be able to treat the output of low-grade ores.

There has developed a great rivalry for lead ores and that class of ore which has hardly paid treatment charges has taken such a big bound forward that a handsome profit can be made out of them. The smelters are making good offers to both the ore buyers and the miners, and leasers are trying to secure mines producing lead ores. The camp has an abundance of this class of ore and work in such mines will alone cause great activity.

MOLLIE GIBSON REPORT.—The annual report of the Mollie Gibson Mining Company was made public last week. It has been awaited anxiously for some time. It is quite lengthy. The report shows that, while not comparing with other years, there has been a fair profit from the ores mined. The development work has been largely confined to the prospecting of a comparatively limited territory above the tenth level. About September 1st there was discovered in the ninth level about the only extensive body of ore opened up during the year. Six weeks of stoping netted about $150,000, but the ore was cut out by a horse, which stopped the dividends, which had been resumed.

The report shows further that the gross amount of ore extracted was 12,425,812 pounds, which contained 764,120.94 ounces of silver. This had a gross value of $460,452.47, but the net cash returns, after all smelting and other charges, was $356,881.27. The company now has $175,780.17 in the treasury, besides many other valuable assets.

SALE AT ASPEN.—The Free Silver property and fifteen acres of the Williams ranch which underlies the end lines of the Smuggler ground has been sold to the owners of the Smuggler property for $200,000.

IDAHO.

REPORTED STRIKE IN THE ALTA.—A Boise, Idaho, dispatch reports a strike in the Alta mine at De Lamar. An air shaft is being sunk. Some time ago it struck into mineralized matter, apparently a flat vein, similar in that respect to the other veins in that vicinity. Sampling and assaying are said to show that the average value of the first fifty feet of ore is $27 per ton in gold. The next eight feet averages $70 per ton in gold. Below this the shaft has penetrated two and one-half feet of ore that has not yet been assayed, but which shows to be very rich. The Alta mine adjoins the De Lamar mine. It was recently bonded to Dutch parties, who have transferred the bond to Chicago capitalists.

MONTANA.

A SURFACE STRIKE.—Warren Decamp has struck a good prospect on the Halford ranch, about 1000 feet east of the shaft he has been sinking during the winter, says the Lump City (Mont.) *Miner*. At a depth of seven or eight feet ore was encountered which assayed 162⅔ ounces per ton. A surface assay went $20, and the improvement has, therefore, been very rapid. The quartz is fine-looking, the walls well defined, starting down as true as if formed by human hands. The lode is strong, wide one, and gives evidence of widening with depth. The pay streak is from eighteen to twenty inches in width, and if it holds its own or improves as the shaft goes down, Mr. Decamp will have a bonanza from the grass roots. As it is it is one of the most important strikes that has been made, on the surface, in the history of the camp.

TWO LUMPS OF GOLD.—Helena *Independent*: Bennett, of Granite county, passed over the counter of an assay office yesterday two retorts of gold, the value of which will run something over $6,000. There were 380.95 ounces in the two retorts, worth about $16 an ounce. The gold was the result of thirteen and one-half days' run of the ten-stamp mill of the Royal Gold Mining Company of Granite county, of which Mr. Bennett is the principal owner. Since the Royal started up in August, 1893, it has not been shut down over two months. In the past year it has paid $105,000 in dividends.

NEW MEXICO.

KEYSTONE MINING DISTRICT.

The Keystone mining district is on the western slope of the Culebras mountains, and is coursed by many living streams, capable of driving many stamp and saw mills. Among the more important streams are Bitter creek, Lost Trail creek and the Red river. A dense timber growth covers the mountain sides, furnishing fuel, building lumber and railroad ties. The district abuts on the east on the Costilla grant, the top of the range being the boundary established by government survey, and is quite near the camp La Belle on the grant.

The first locations in this vicinity were made in the La Belle district on the grant. But the miners were so hampered by restrictions of the grant company that last September some of the miners left the La Belle district to prospect on the other side of the Culebras range.

OREGON.

BAKER.

LEASED TO CHINAMEN.—The Archie Downie claims, near the Sumpter, have been leased by the owner to Chinamen who are to pay a royalty of $300 per week during the working season.

TO RESUME.—*Democrat:* B. N. A. McMillan, manager of the Beckwith Mining Company, is at the Beckwith mine looking after a resumption of operations on an extensive scale in the near future.

CLAIMS SYNDICATED.—*Democrat:* Fourteen of the principal placer claims along the Grande Ronde river have syndicated and it is expected that some outside parties will arrive in a few days to examine the same with a view of closing a deal for the entire lot. H. A. Burns, of La Grande, has been appointed an agent for the sale of the same.

NEW IN OREGON.—*Times:* The Company in which Judge Reid, W. W. Milner and C. O. White of Tacoma are interested, started operations at their mines near Tolo this week. The steam pumping apparatus, which furnishes a fine supply of water from Rogue river, works to perfection and inaugurates a new system of mining.

GALL'S CREEK DISTRICT.

RICH LEDGE.—Lawrence & Cameron of Gall's creek have a rich ledge, and recently had eleven tons of the ore crushed at the Lindley mill on Sardine creek, from which was obtained $4,800 in gold or nearly $440 a ton. Gall's creek is one of the richest districts in Oregon, but very few well-defined ledges have as yet been found, pockets predominating.

GENERAL SOUTHERN OREGON NOTES.—Birdsley & Co., of Kane's Creek district, have resumed piping, the late rains having brought sufficient water.

Frank Knight has traded his interest in Kuhli & Co.'s mine in Gall's Creek district for another promising ledge on Galice creek.

J. B. Dyer has bonded the Shepherd quartz ledge on Emigrant creek, and is engaged in making preparations to develop the mine.

The Homestake mine, in Woodville district, is prospecting well and work is being pushed on it.

Schrimpf Bros., of Williams Creek district, are working in ore which produces an average of $20 a ton.

Bailey & Co., owners of the Mountain Lion mine in Missouri Flat district, will soon resume work.

The boiler and engine of the Hosley mill, on the Siskiyous, were shipped by John R. Stearns last week to the Songer & Dame mine on Klamath river, which will be operated on a large scale.

James Wyatt and Scott Gall, of Sam's valley, have struck a quartz ledge on Fitzgerald mountain, which promises to be rich. Samples of the ore have been estimated by experts to assay $80 per ton.

Work has been resumed in the Anaconda mine, in Josephine county, by Mr. King and Arch Taylor, of Grant's Pass. Prospects are good. The Bone of Contention still lies idle, awaiting the return of J. C. Ezzell.

The stockholders of the Hammersly mine, in Jump-off-Joe precinct, held their annual meeting at Medford last week. Officers were elected as follows: President, G. R. Hammersly; vice-president, A. S. Hammond; secretary and treasurer, J. L. Hammersly; general manager, Riley Hammersly. Although the mine is bonded the company will work portions of it until final payment is made.

UTAH.

A PROFITABLE INVESTMENT.—*Tribune:* A cyanide gold mine and mill turning out $22,000 in fourteen days, against an expense of not more than $4000, is one of the interesting phenomena that Utah is now presenting to the mining world. To all appearances that record can be made continuously for an indefinite length of time. The people to profit by it are those lucky Nebraska gentlemen, who one year or more ago invested in the Mercur mine at Camp Floyd.

The recent article from the pen of Dan De Quille should have been credited to the Salt Lake *Tribune*.

WYOMING.

THE TAIT MINE SOLD.—A big mining sale has just been made in the Wood River country in Wyoming. The Tait mine and a few adjoining claims have been sold to some Eastern capitalists for $65,000. Of this sum $25,000 is to be paid in cash and the remaining $40,000 when the stamp mill is ready for operation. The original owners will also receive a royalty of fifteen per cent on the mill product. The mine, which is a good proposition, is situated on Franc's Fork. The lead is twenty-five feet in width and assays $6.75 free gold to the ton. The mine is situated at almost an inaccessible point in the mountain. All material and supplies have heretofore been taken in on pack animals. The new owners will build a road. It will cost $30,000 of itself. The mine is but three miles from the boundary of the Yellowstone Park.

PLACER DEAL CLOSED.—A party of Rhode Island capitalists, who visited the Dry Gulch placer district on Snake river, has closed the deal for 1500 acres of placer ground. The purchase price, including the ditch, is a little less than $120,000. The money was paid lately. They have purchased the Douglas water right, which taps the Snake river at Dixon. The contract for extending the ditch has been let to a prominent firm of railroad contractors who will ship men and teams, which were expected to arrive last Monday. A new town will be laid out at Dry Gulch, fifteen miles west of Baggs. Work will begin at once, and will be pushed with all possible speed.

ACTING Secretary of the Treasury Hamlin has decided that diamond cutting in the United States is not a new industry. Consequently the expert diamond cutters whom it was proposed to bring over from Holland to New York to ply their avocation in this country may not be admitted under the contract labor law.

IT is believed by competent judges that in times of normal prosperity the demand for all-around machinists for work on new devices and special machinery equals the curtailment of work requiring their skill in shops, due to the installation of automatic machinery which machine hands can operate equally well.

COCKROACHES are never wittingly slain by Chinamen. They consider them sacred insects, and think it portends ill luck to step on them. As they never make any effort to exterminate them, the Chinese quarters are usually overrun with these pests.

EVERY steam pipe supplying an engine should be provided with a drip close above the throttle valve, that is, if the pipe descends to the engine. If it comes below, of course, the drip will have to be from the lowest point in the steam main.

IT is said that there are millions of Chinese in the interior of China who are totally ignorant of the fact that a war has been going on with Japan.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 26, 1895.

536,254.—DISH WASHER—E. H. Alvord, Seattle, Wash.
536,267.—BUCKLE—C. A. Conger, S. F.
536,186.—COAL BUNKER—Curtis & Isaacs, S. F.
536,376.—PIPE—R. F. Dockery, Los Angeles, Cal.
536,194.—STEAM ENGINE—W. R. Dow, Alameda, Cal.
536,465.—RAILWAYS—E. Gay, Riverside, Cal.
536,466.—VOTING MACHINE—F. H. Gilbert, Ridgefield, Wash.
536,284.—CAR COUPLING—C. W. Hinton, Los Angeles, Cal.
536,210.—SIGNAL—W. E. M. Jackson, S. F.
536,576.—SKIRT ELEVATOR—J. Mallett, Oakland, Cal.
536,226.—SEPARATOR—J. D. McKinnon, Portland, Or.
536,233.—TELEPHONE—Sabin & Hampton, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

WINDMILL.—Charles A. Norcross, Reno, Nevada. No. 535,956. Dated March 19, 1895. This invention relates to certain improvements in windmills. It consists in the employment of two oppositely rotating wheels mounted close together upon the same shaft, so that the wind passing through one wheel reacts to turn the other wheel in the opposite direction; and in conjunction with this an intermediate mechanism by which the power of each wheel is transferred to a vertical driving shaft, the proportion of the mechanism being such that while the two wheels rotate at different rates of speed, the power will be applied essentially evenly to the vertical shaft. The vanes of the wheels are made by stretching metal sheets around the radial straining rods and interior to a supporting rim, the edges of which are turned around peripheral rods.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents Inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliable.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the globe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

LUNKEN HOSE GATES.

The best and most practical Hose Gate on the market. SIMPLE, COMPACT, DURABLE, **LOW PRICED.** ¾-inch to 3 inches, with and without finished cap and chain. ACCEPTED BY THE INSPECTION DEPARTMENT OF THE ASSOCIATED FACTORY MUTUAL INSURANCE COMPANIES. **It will pay you to investigate this Valve. Write for prices and sample.** SATISFACTION GUARANTEED. Catalogue of numerous "up to date" Steam Specialties, gratis upon request.

Electrical Progress.

An Important Enterprise in Mexico.

A most interesting and important electric-power installation is now under construction for the Cia. Anonima de Transmission Electrica de Potencia, located in the State of Hidalgo, some 100 miles north of the city of Mexico.

The water is taken from the Arroyo de Regla, a mountain stream having a minimum supply of 1500 cubic feet per minute. A natural rock dam at a point in the canyon impounds the water sufficiently to admit of its being diverted by a cut through the bluff into a canal which follows mostly the contour of the mountain—a distance of 1½ miles. This involved the cutting of seven tunnels, aggregating a total length of 1200 feet through solid rock.

From the terminus of the canal the water is carried to the power station through 1700 feet of thirty-inch pipe, which affords a vertical head of 800 feet, this being of varying thickness to correspond to the pressure at various points on the line, the lowest portion being made of steel three-fourths of an inch thick. The pipe line discharges into a receiver forty inches in diameter by seventy-five feet long, with which the wheels are connected by lateral branches. This is made of flange-steel plates three-fourths of an inch thick, tested to 700 pounds water pressure, and weighs upwards of 50,000 pounds.

The power station consists of five Pelton wheels, forty inches in diameter, of capacity of 400-horse power each, directly connected to the same number of twelve-pole, three-phase generators running at a speed of 600 revolutions, delivering the current at a pressure of 700 volts; also two twenty-four-inch Pelton wheels speeded at 1700 revolutions for running the exciters. The step-up transformers are wound for a ratio of one to fifteen, making the line potential a little over 10,000 volts at the generator end. There are three transformer sub-stations in which air-blast transformers are to be used. Pelton differential governors are attached to each wheel for the purpose of regulation.

This station is to supply power to the mines of the Rio del Monte Company—one of the most extensive mining organizations in the world, employing upwards of 8000 men. The power is to be used for operating mining machinery, such as stamp mills, crushers, pumps, hoists, ventilators, etc. The mines of this company, said to be the richest in Mexico, are located within a radius of twenty miles, the maximum distance of power transmission being twenty-three miles and the mean distance about eighteen miles. Various other mines in the vicinity will also be supplied with power from this station and the city of Pachuca also furnished with light. A market for the entire power being thus afforded at highly remunerative rates, the financial success of the enterprise is assured—in fact, it is claimed that the entire outlay, some $300,000, will be returned to the company in two years' time from the saving effected in fuel heretofore required in carrying on their various operations.

This important enterprise, involving many difficult engineering problems, originated with and is being carried to completion under the direction of Senor R. M. de Arozarena, an accomplished engineer, resident of the city of Mexico, also a director of the company.

The Pelton Water Wheel Company, of San Francisco and New York, has the contract for the hydraulic part of the work, and the Thomson-Houston International Company, of New York, for the installation of the electrical machinery. The plant is expected to be in running order in about ninety days, when some further particulars will be given as to its operation.

Considering the magnitude of the work, the extreme water pressure, the variety and extent of machinery to be operated, as well as the difficulties attending the transportation and erection of such massive machinery in a mountainous and almost inaccessible region, this may be regarded as altogether the most remarkable electric-power installation so far made in any part of the world.

The Legal Aspects of Electrolysis.

It is at the present time a well-settled fact that a continuing and serious damage is done to buried gas and water pipes and to the metal sheaths of buried telephone and other cables by the action of electricity as now generally employed by electric railway companies for propelling their cars, and, while efforts are being made to obviate the trouble, the success of the remedies proposed or their suitability for constantly changing conditions is somewhat doubtful, so long as the rails are employed as a part of the electric return circuit.

It is generally admitted that a complete remedy is found in the use of a return circuit entirely insulated from the earth, such as would be afforded by the use of a double trolley wire; but there is a natural aversion on the part of the street railway companies to such an expedient because of its expense, although it may be seriously questioned whether the deterioration or corrosion of the rails themselves, when buried in the earth and used as a return circuit, is not a source of loss whose magnitude, if fully appreciated, would virtually compel the adoption of this remedy.

The disposition, however, is to palliate the evil, if possible, by improving the conductivity at the rail joints, thereby furnishing so good a path for the return current that the amount diverted to the earth and to buried conductors will not produce a material injury. The injury arising from imperfect bonding had, however, grown to be very great before the extent of the evil had been suspected, and will continue to exist wherever the bonding is imperfectly done or where it may deteriorate.

The question arises on this general state of facts: Upon whom does the responsibility rest for the injuries heretofore accruing, or which may hereafter arise, from the corrosive action of the railway currents? This question Henry C. Townsend discusses in a very suggestive and interesting manner in the April number of *Cassier's Magazine*, analyzing the subject from an expert's standpoint and indicating what may be expected in the way of compensation from electric street railroad companies for damages resulting from their power circuits.

Electricity in the Seventies.

The rapidly growing interest of the public in things electrical is being met by a much higher standard of electrical information in the leading daily papers, and one result of this popular education is that it is by no means an uncommon thing to hear practical electrical questions discussed with much intelligence by those who have had a technical training. This is the more noticeable when the dense ignorance in regard to the phenomena of electricity which reigned outside of professional circles not many years ago is considered. C. F. Brush, who is well known as one of the pioneers of electric lighting in this country, recently told a convention of the National Electric Light Association something of his experience in 1878, when the first arc-lighting machine was started in Cincinnati. The light was exhibited from a balcony on one of the principal streets. It was a 4000 candle light, and, of course, it attracted a large crowd of the natives. A singular point about the crowd was that every man in it seemed anxious and ready to tell his neighbor all about the wonderful new light. One man collected quite an audience about him. He called attention to the solenoid at the top of the lamp. "That," he said, "is the can that holds the oil;" and speaking of the side rod of the lamp, "that is the tube which conducts the oil from the can to the burner." He said nothing whatever about electricity, but the oversight was not noticed by his hearers. One of the earliest lighting machines was about the same time taken to Cleveland, where it was shown in operation to a number of invited guests by a local engineering firm.

One of the guests looked the whole apparatus over very carefully for about half an hour, and then, pointing to the line wire, said to Mr. Brush: "How large is the hole in that wire that the electricity flows through?" Another spectator, who was connected with the company in whose works the machine was being shown, watched its operation for about five minutes in silence. By that time he had digested the whole thing and was ready to tell Mr. Brush all about it. He said: "The electricity in that thing is generated by that revolving business there, rubbing the air up against these iron blades (meaning the field magnets) just as you get sparks when you rub a cat's back." Mr. Brush ventured to remark that, while that might be a good theory, it did not fully meet the facts. The objection was promptly put aside: "The whole thing is plain. If you should run that machine in a vacuum, where there is no air, you could not get any electricity." Mr. Brush related another incident illustrative of the vagueness of the popular ideas of electric light in the pioneer days. When the first commercial arc lights were installed in Cleveland, the "tower" system was used. Twelve lights of the so-called 2000 candle power were massed on the top of high ornamental poles in the Public Square. At the first illumination the little park was packed from side to side, and many of the people, in expectation of a blinding glare of light, had provided themselves with colored spectacles or smoked glass.

Electrical Terms.

People read every day about volts and amperes without understanding in the least what they mean. A prominent legal cross-examiner makes this clear, and he does it by telling of the question he put to Mr. Thomas A. Edison in the witness-box one day. Here is the question, and Mr. Edison's answer:

Q. "Explain what is meant by the number of volts in an electric current?"

A. "I will have to use the analogy of a waterfall to explain. Say we have a current of water and a turbine wheel. If I have a turbine wheel and allow 1000 gallons per second to fall from a height of one foot on the turbine, I get a certain power—we will say one-horse power. Now, the one foot of fall will represent one volt of pressure in electricity, and the 1000 gallons will represent the ampere or the amount of current; we will call that one ampere. Thus we have 1000 gallons of water or one ampere, falling one foot or one volt, or under one volt of pressure, and the water working the turbine gives one-horse power. If, now, we go 1000 feet high, and take one gallon of water and let it fall on the turbine wheel, we will get the same power as we had before, namely, one-horse power. We have got a thousand times less current or less water, and we will have a thousandth of an ampere in place of one ampere, and we will have 1000 volts in place of one volt, and we will have a fall of water 1000 feet as against one foot. Now the fall of the water, or the height from which it falls, is the pressure or volts in electricity, and the amount of water is the amperes. It will be seen that 1000 gallons a minute falling on a man from a height of only one foot would be no danger to the man, and that if we took one gallon and took it up 1000 feet and let it fall down it would crush him. So it is not the quantity or current of water that does the damage, but it is the velocity or pressure that produces the effect."

Timhering in Mines.

The timbering of mines is a very important item in connection with mining, and it has been frequently evidenced that in this particular large quantities of timber are wasted and a great deal of unnecessary expense is incurred. We have mines in view where a slipshod system of timbering has resulted in what might be called a wasteful outlay, and where a more intelligent mine manager has been able, by care and attention, to greatly decrease this item upon the bill of operating expenses. The percentage of cost for timbering varies greatly in different mines, according to the system of timbering adopted. It is interesting to note in this connection that many mines are timbered with cedar, which in its turn is mined, strange as it may be, from a timber mine. In the State of New Jersey there are spots where vast quantities of timber have lain for ages, which, when dug out of the ground, is found to be intact and to all intents and purposes as firm and sound as if it were recently cut wood for building purposes. The question arises, How did the timber get there? The theory is that a vast timber forest was laid low by some conflict of nature, and then covered up by an upper stratum of earth which has succeeded in preserving the trees, the first of which was discovered some years ago. It is interesting to note that the system of mining consists in first locating the tree with a rod and then digging a trench along its length and by filling the said trench with water, causing the tree to rise. It is said that trees have been discovered at the depth of eighty feet. On the vegetable theory of the origin of coal this should be indeed a magnificent illustration of its early state.—Black Diamond.

New Remedy for Insomnia.

An expert in nervous disorders in Paris recommended to an American gentleman a cure for insomnia which was tried with such success that the patient has prescribed it to many of his friends. It is simply to keep your eyes open when you want to go to sleep and cannot. A person whose brain is too active will sometimes close the eyes and vainly endeavor to sleep. The very closing of the eyes seems to concentrate the mental faculties on business affairs and other distractions. The theory of the French physician is that if the victim of insomnia will fix his eyes upon some gleam of light, some shadow, or even on the darkness itself, he can relieve his mind from thoughts that perplex it and divert attention from himself. Try the experiment when you are sleepless and see how unconsciously your eyes will close and your thoughts begin to take possession of you. Struggle to keep them open and fixed upon an object, either real or imaginary, and before you are aware of it the struggle will have ended and sleep will be victorious.

A Long Life.

Sir Benjamin Richardson, M. D., of England, thinks that the normal period of human life is about 110 years, and that seven out of ten average people could live that long if they lived in the right way. They should cultivate a spirit of serene cheerfulness under all circumstances and should learn to like physical exercise in a scientific way. No man, he says, need be particularly abstemious in regard to any article of food, for the secret of long life does not lie there. A happy disposition, plenty of sleep, a temperate gratification of all the natural appetites, and the right kind of physical exercises, will insure longevity to most people.

COMMON salt is one of the most valuable remedial agents the world contains. Used as a tooth powder, alone or with a little prepared chalk, it whitens the teeth and makes the gums hard and rosy. It is a good gargle for sore throat, and if taken in time will benefit, if not cure, diphtheria. It will stop bleeding of the mouth, and in warm water is a good emetic and remedy against several poisons. There is nothing better for sore feet and hands than salt and water, and for ordinary sore eyes, though a painful application, it will often effect a complete cure.

GEORGE T. COMINS, the manager of the Beecher Falls, Vt., mill, on the U. S.-Canada line, relates an amusing story illustrative of the contract labor laws. It seems that the company's logs are stacked up in tiers about three feet apart on both sides of the line. One day recently the foreman was standing on one of the piles when a man approached and asked him if he wanted to hire any help. He replied that he did not, at the same time stepping over to the next pile. The man followed him, when the foreman turned and said: "When do you want to go to work?" "I thought you didn't want to hire anybody," said the man. "I was in Canada then," the foreman said, "and liable to a fine of $1000.

THE peculiar accident to the steamer Venetian, near Boston, by which the vessel was broken in two in the middle, suggests again the danger of great length in metal ships. There seems to be a lack of what might be termed longitudinal strength in vessels made of plates of iron or steel. The strain to which the craft is subjected when raised upon a wave is hardly less than that to which the Venetian succumbed.

THE salary of the President of Mexico is $30,000.

PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, April 4, 1895.

The advance in silver during the week attracted universal attention. Monday's price was 68 cents an ounce—the highest since Jan. 20, '94. Possibility of favorable legislation, the proposed hi metallic conference, and the expectation of sudden demand for considerable quantity of silver in the case of the Chinese indemnity, were among the causes for the rise, which cannot he considered other than a spurt, the speculative character of the advance not warranting any assumption of permanence or tangible effect in the settlement of the great question. The advance has been the occasion of justly joyful comment all over the west half of America. It is very likely that were the price to advance to 70 cents a large number of idle silver-producing properties would resume work.

Every three months the Treasury Department fixes the import value of foreign coin for the ensuing quarter; this time the quarterly value was announced just before the little "hoom" in silver, with the curious result that while Mexican dollars are quoted 54@55 cents, the official valuation is $0.479. Importers of Mexican dollars will not he slow to take advantage of the situation.

New York Metal Market.

NEW YORK, April 4.—PIG IRON—Scotch, 19@20c; American, 9.50@12.50c.

The Golden Eagle is in debt $7481.46, and the Summit $533.35.

Sales at the regular session of the San Francisco Stock and Bond Exchange Board for the month of March were 286,530 shares. For the first three months of the year they were 737,545 shares, as against 730,000 shares during the same period last year.

At the delinquent assessment sale of the Seg. Belcher Mining Company 2575 shares were sold for non-payment of assessment.

At the delinquent assessment sale of the Justice Mining Company 1188 shares were sold for non-payment.

The North San Juan Gold Mining Company of Nevada has levied an assessment of 12 cents per share, delinquent May 6.

The Gold Point Consolidated Gold and Silver Mining Company of Nevada County has levied an assessment of five cents per share, delinquent May 1.

Next week the Bodie mill will begin crushing an accumulation of ore from the Bodie Consolidated mine.

An assessment of twenty-five cents per share has been levied on the Ophir.

The following illustrates the changes of the week:

LIGHTNING AND LARGEST WELL MACHINERY Works.
All kinds of tools. Fortune for the driller by using our Adamantine process; can take a core. Perfected Economical Artesian Pumping Rigs to work by Steam, Air, etc. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from David Croft, in the Gold Deposit mine, near Kelsey, El Dorado Co., to deposit tailings in an old hydraulic pit; from Wm. F. Coe, in the Railroad Placer Mine, near Placerville, El Dorado Co., to deposit tailings behind dams in Spanish Flat Ravine; from J. C. Day, in his mine near Georgetown, El Dorado Co., to impound tailings in an old hydraulic pit; from John A. Browles, in the Independence Mine, near Brownsville, Yuba Co., to impound tailings behind a dam in Letson Ravine; from Wm. Henning et al, in the Iowa Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jas. Ward & Wm. McDonald, in the Tiger Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jos. J. Hoffman et al., in the Hard Times Mine, Bath, Placer Co., to impound tailings in an old hydraulic pit; and from Wm. & Wm. J. S. Bacchi, in the El Dorado Placer Mine, Garden Valley, El Dorado Co., to impound tailings in ravine below the mine, gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, on April 22d, 1895, at 1:30 P.M.

THE CALIFORNIA DEBRIS COMMISSION having received an application to mine by the hydraulic process from George Wheeler, in the Grizzly Flat Mining Claim, El Dorado county, Cal., to impound tailings behind brush dams below the mine, gives notice that a meeting will be held at room 92, Flood building, San Francisco, Cal., April 1, 1895, at 1:30 P. M.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

SECOND HAND
Mining Machinery Wanted.

TWO 5-STAMP BATTERIES,
Single discharge, quick drop.
Also FOUR FRUE VANNERS.
Must he in good condition and of late pattern.
Address Box 584, Leadville, Colo.

L. C. MARSHUTZ. T. G. CANTRELL.

Coast Industrial Notes.

—The Paraffine Paint Co. has paid its regular quarterly dividend of 25 cents per share.

—Charles F. Martin, at 223 Mission street, has had granted to him a patent on a flying machine, on which he has been working for two years.

—W. P. Fuller & Co. have finally quit fighting the Standard Oil combine, and coal oil, gasoline, etc., have advanced one cent a gallon. The coast consumes about 20,000,000 gallons annually.

—The fact that there is a grain of gold in every ton of sea water impels a Colorado corporation, called the Carbon Precipitating Co., to establish works at San Diego to secure gold from the waters of the Pacific ocean.

—Everett, Wash., expects soon to see work begin on a new whaleback. Estimates on the earnings of the whaleback City of Everett show a net profit of $5000 a month. This would provide for 20 per cent yearly dividends and pay for the boat in five years.

—Hall Bros. are building three four-masted schooners at Port Blakeley, Wash., each to be about 3000 tons burden, with a carrying capacity of 700,000 feet of lumber, and costing $40,000. This firm has now built eighty different vessels of fir and with universal satisfaction.

—T. W. Jones is at Newcastle, Placer Co., in charge of the work of putting in an electric light plant for the South Yuba Water Company. The dynamo house will be erected on the hill, a mile from town. The plant will furnish light for Newcastle, Penryn and Rocklin.

—The Sloss-Wasserman trial in progress reveals the enormous dividends made by the Alaska Commercial Company out of its sealing contract. Dividends amounting to $800 on every $100 share were paid for five years. The firm had millions on deposit, acquired by the capture of seals. Sloss bought some of the shares from Wasserman for $60 each.

—The work of grading on the narrow gauge railroad from Carbondale to Amador has begun. It is claimed the work will be pushed through to completion as soon as possible. It is announced as the intention to have this road connect with Jackson, Sutter Creek, Amador City, Plymouth and other towns on the mother lode, and be extended up into the timber region in the Sierras.

For the first time a carload of flowers was, last Wednesday, shipped to the East by freight from Los Angeles, via the Santa Fe, to Chicago, where the blossoms will be used in Easter celebrations. The shipment will make the trip in six days, going on a fast fruit train. The shipment comprises, among other items, one of 30,000 Calla lillies and several thousand caruations. Lilies can be landed in Chicago for between $6 and $7 per thousand and will bring $50.

—The San Joaquin Electric Company incorporated this week at Fresno, with a capital stock of $800,000. The incorporators are J. J. Seymour, O. J. Woodward, J. S. Eastwood, James Porteous, W. R. Madary and L. L. Levy. The company proposes to construct a dam eighty feet high on the San Joaquin river, near the mouth of Fine Gold creek, thirty-two miles east of Fresno, and utilize the power for electric lighting and motor purposes.

—Preparations for the opening of the Columbia river salmon-packing season are complete. On April 10th nearly every cannery on the Columbia river from The Dalles to Astoria will present a scene of activity. Packers generally are anticipating a good run of fish, and, as the market demand is steady at last year's prices, they are ready to stow away every chinook that can be had. The season will open with a rush, and the rush will continue right through the next three months.

—Mr. C. C. Howell, the manager of the Sacramento Industrial Improvement Association, says that under arrangement with the Sacramento Electric Light and Power Co., an electric current equivalent to 10-horse power will be furnished a manufacturer in that city for $587.20 a year, or $47.93 a month, for ten-horse power, ten hours a day, for twenty-six working days a month and twelve months in the year. If this is so, there is no other place in the country where power can be secured so cheaply.

—A new steamer line from Portland to Japan is announced. The O. R. and N. Co. have an agreement with Samuels, Samuel & Co., of Yokohama, and others, to place two steamers on the route, making monthly trips. The first steamer leaves Hong Kong the 1st of May. The first steamer leaves Portland June 1st. All steamers will run via Yokohama and during the winter months via Honolulu. The vessels are to have a carrying capacity of from 3000 to 5500 tons. The line is to be operated in connection with the O. R. and N. Co. exclusively.

—The high price of fuel makes manufacturers look with interest at the possibilities of southern California oil wells, and desirous of investigating the renewed project of transmission of power from Clear Lake, 73 miles from here. Engineers, who have given the matter considerable attention, say 75,000-horse power can be developed. It is now proposed to transmit 5000-H. P. to Benicia, and the possibility of transmission across the bay from Oakland is under discussion. That the successful solution of the question would greatly simplify the fuel problem, which is really the power problem in this city, is manifest.

—The failure of the Canadian Pacific railway to pay dividends on its common stock is not a surprise to those who have known that the Canadian Government has for years loaned to this company the money for dividends. All this time the debt of Canada has been growing, but it was supposed that the mortgage on the property and bonds of the railroad would prove a good security. For a while, in years of its prosperity, it is probable that the dividend was earned. Money was also raised by the issue of new stock, ostensibly to pay for new lines and equipments. Part of this money went to pay dividends. The last three years the earnings of the company steadily declined. In 1892 they were $21,400,000. In 1893 they were only $20,362,000, and last year there was a drop to $18,700,000. From 1884 to 1893 the capitalization of the the company increased from $100,000,000 to $177,000,000. The dividends on the stock were guaranteed by the Dominion Government from 1883 to 1893, and with the expiration of the guarantee the dividends ceased. The railroad has been the chief backer of the MacDonald and the Thompson administrations. If the Liberals come into power, as they are likely to do, the road will not further involve the people of Canada in debt. The Canadian debt in 1870 was $173,000,000, but in 1889 it was $286,000,000, and on June 30, 1893, it had increased to $300,000,000. This is about $60 per head for man, woman and child. The debt is increasing, while emigration to the United States makes the Canadian increase in population very slow. At least 1,000,000 natives of Canada are now living in the United States.

ALUMINUM is found to be not suitable for a great many of the uses to which it was to be put.

Assessment Notices.

BRUNSWICK CONSOLIDATED GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley Mining District, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 20th day of March, 1895, an assessment (No. 8) of Two cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room 56, Nevada Block, San Francisco, California, or to the Treasurer, F. J. Halpin, 57 Broadway, room 87, New York City, State of New York, on or before the 20th day of April, 1895.

Any stock upon which this assessment shall remain unpaid in San Francisco, on the 20th day of April, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. STADTFELD Jr., Secretary.

Office—Room 56, Nevada Block, San Francisco, California.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 20th day of March, 1895, an assessment (No. 18) of Ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 69, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

IOWA MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia City, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 6th day of March, 1895, an assessment, (No. 20) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 2, 419 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 9th day of April, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 27th day of April, 1895, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. L. THOMAS, Secretary.

Office—Room 2, 419 California Street, San Francisco, California.

DELINQUENT SALE NOTICE.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Auburn, Placer County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 5) levied on the Eighteenth day of February, 1895, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
Richard Chenery, Trustee	160	6,275	$125 50
Richard Chenery	17	5	10
Thomas Day, Trustee	148	500	10 00
Thomas H. Gordon, Trustee	68	1,000	20 00
Thomas H. Gordon, Trustee	112	100	2 00
Thomas H. Gordon, Trustee	114	100	2 00
Thomas H. Gordon, Trustee	116	100	2 00
Thomas H. Gordon, Trustee	117	100	2 00
Thomas H. Gordon, Trustee	118	100	2 00
Henry Gilman	28	300	6 00
Henry Gilman	175	1,000	20 00
E. S. Harrison, Trustee	177	1,000	20 00
J. W. Winter, Trustee	161	250	5 00

And in accordance with law, and an order of the Board of Directors, made on the Eighteenth day of February, 1895, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the salesroom of S. P. Middleton & Co., No. 30 Montgomery Street, San Francisco, California, on WEDNESDAY, the Seventeenth day of April, 1895, at the hour of Two o'clock P. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

GEO. R. SPINNEY, Secretary.

Office—310 Pine Street, Room No. 28, San Francisco, California.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

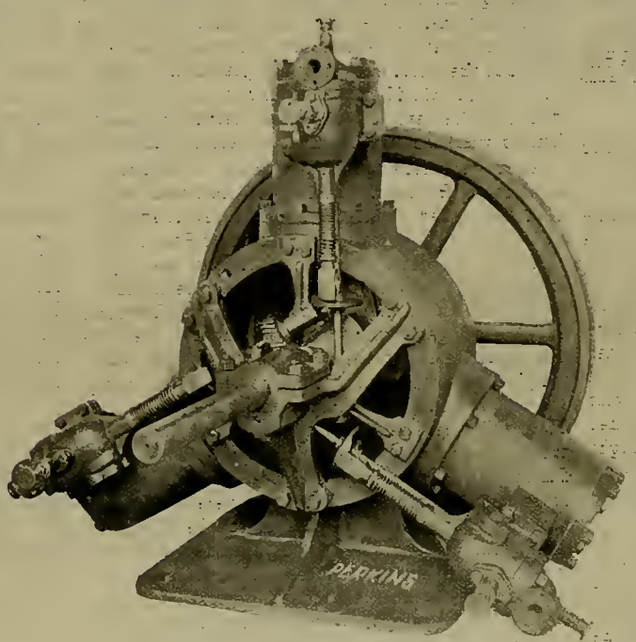
A Very Big "Boom."

A California mining man now in London writes that no one not on the spot can form adequate idea of the present craze in the British metropolis for South African mine shares and at absurd prices. He says that every shopkeeper is buying, in many instances realizing on valuable securities to put money into the most inflated schemes. The "Kaffir Circus," as it is called, is a present popular investment, and staid and respectable Britons talk of the "boom" and buy shares in real and fanciful mining propositions that as a matter of airy speculation beat anything ever heard of on this coast. The London *Mining Journal*, an old and conservative concern, has as "boomy" and airy a tone as ever was evinced in the local columns of a Nevada paper in the old days when Con. Cal. and Va.'s 108,000 shares were split up into 540,000, and each one paid a monthly dividend of $2. In the issue of that paper to hand, dated March 16th, it says in a leading editorial: "It is impossible to dismiss the movement contemptuously as a 'mining boom,'" and argues that the Rand has "an even more wonderful future," and that "the glowing forecasts of a few years ago are feeble underratings of the facts which seem to be established by later developments." And so on. This old and influential journal thinks that even the blocks of stock now being dealt out to French investors at "way up" figures will be soon bought back by English capitalists "at enhanced values," and that Rand mine properties will go to twice their present valuation. Perhaps so. When a usually conservative mining paper like the *Journal* editorially believes that, it is not strange that every one in London with a few spare pounds in his pocket should be falling over each other in a mad rush for stock in the South African mines. Meanwhile we must differ from our esteemed British contemporary in its belief that the present wild purchase is not "speculation." If it isn't, then what is "speculation"? Without at all questioning the acknowledged value of some South African gold properties it is as certain in this instance, as it has always been in every other similar instance, that a good many good people will be fooled into buying worthless stock, and that the inevitable reaction will injure the placing of legitimate mining enterprises located in South Africa or, in fact, anywhere else.



PERKINS TRIPLEX GAS ENGINE.

Borax.

Like some other California productions the borax industry is not particularly active just now. The borax deposits in this State and Nevada have been worked for the past twenty-three years, a vastly larger proportion of the total production being from California borax marshes and beds during the past four years. The different borax companies have derived nearly all their product from "marshes." Near Daggett, in San Bernardino county, borate deposits of an entirely different character have been partially developed, being found in hard, dry, stratified masses among sedimentary rocks. In the southern part of Inyo county, borates of lime and soda are being worked at Salt Wells valley. Cuts of the works and of the team used in hauling from the mine thereto, typify the desolate desert character of that region.

Perkins Triplex Gas Engine.

The accompanying cut illustrates an original departure in construction and operation from the ordinary form of marine gas engines, its object being to attain high speed and great power within limited space. This is accomplished by frequent explosions within the three cylinders giving such rapid and successive play upon the crank shaft as to constitute an almost unbroken explosive action. By this means the engine is started with great ease, maintaining a steadier and more uniform motion than any other engine of this class, and equaling, it is said, that of steam. While its compactness and steadiness peculiarly fit it for marine uses, it is also especially adapted to operating dynamos for lighting or other purposes. The subject of the accompanying illustration was built on a special order for Commodore Leonard's sloop yacht "Dream," as an auxiliary to sails. It occupies but four feet of space in any direction and develops eight H. P., with working revolutions of 300 per minute. The construction and operation is simple and economical, and as a marine type of gas engine it will doubtless prove a success and come into general use. This engine was built from the designs of Mr. Paul B. Perkins, of the Perkins Pump and Engine Co., 117 Main St., S. F.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Perkins Triplex Gas Engine; Borax Team; Borax Works, Inyo County, 225.
EDITORIALS.—A Very Big "Boom;" Borax; Perkins Triplex Gas Engine, 225. Platinum Production; That Amendment Again; Miscellaneous, 226.
CORRESPONDENCE.—Placer County Mines, 228. Development of Mines, 229.
SCIENTIFIC PROGRESS.—Testing Precious Stones; Decomposition of Water by Iron; Edison's Latest, 232.
MECHANICAL PROGRESS.—The Future Newspaper; An Average Day's Work; Miscellaneous, 233.
ELECTRICAL PROGRESS.—Making Climate as Desired, 236.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 234-35.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 238.
MISCELLANEOUS.—Concentrates, 227. Pocket Hunting in California, 228. Mother Lode Power Company, 229. Description of the Gold Belt of California, 229-30-31. Personal; A Satisfactory Test, 231. Points on Patents to Mines: Tellurium, 237. Coast Industrial Notes, 239.

SIMULTANEOUSLY with silver, cotton, wheat and corn have risen in price in the last three weeks.

TO TALK OF "hard times" is no longer fashionable in the East. The habit continues largely from force of habit, elsewhere.

DENVER PAPERS say that the Mining and Industrial Exposition to be held in that city will be a sure success. It ought to be, and no State will be better pleased thereat than California. Colorado miners have shown good grit, and in developing the gold properties of the Centennial State have turned disaster into victory. The proposed exposition ought to be a grand thing for that commonwealth and result in an enhancement of its general prosperity.

THE possible appreciation in the price of silver to a figure approximating old-time quotations means more to the State of Nevada than to any other mining community. The other States and Territories have developed gold wealth since the slump in the sister metal, but the Silver State has thus far been unable to show the possession of gold ore to anything like the extent necessary to redeem its prosperity from the blight put upon it by the drop in the price of its staple product.

THERE is an unusual movement among gold prospectors, and thousands of men are exploring in every direction. Eastern and southern Oregon, northeastern Washington, central Idaho, the upper Pend d'Oreille, Trail Creek, and north of the Colville reservation, to the headwaters of the Skagit, and coastward along the Alaskan line toward the Arctic circle, an army of men is scattered through the northern country. Throughout the long clear summer the million square miles northward from the California line and eastward from the coast to Lon. 104° W., will be traversed. The lower tier embracing this State, Nevada, Utah, Colorado, Arizona and New Mexico have seen equal activity for the past two years, some of the present best producing claims being the result, and '95 gives promise of greater measure of success. Profitable prospecting will be done even in this State for many years to come. There are mineral areas in California which have never been thoroughly prospected. For there is prospecting and prospecting. The horseback prospector who, with a mounted party, "traveled all over that country ten years ago and saw nothing worth stopping for," is usually heading for somewhere else. Riding through a region is not prospecting it. Men may travel through a section and afterwards condemn it, though they never dug a five-foot hole in any one spot. Wandering around is not prospecting, though there is a nomadic streak in every prospector, he being ever ready to seek new sources of wealth, which is usually enjoyed by some one else.

Platinum Production.

The increasing demand for platinum, more especially in the manufacture of incandescent electric lamps, gives great importance to this metal and its sources of supply. It is widely diffused, being found in almost every mining region in the world, usually minutely disseminated in serpentine rocks or their debris, but only in the Ural mountains, Russia, does it occur in grains, and only in those mines is it thus secured in any considerable quantity with accompanying profit. In Brazil and Colombia, South America, Sinaloa Mexico, various counties in this State and Oregon, and other localities on this continent, native platinum occurs, almost invariably in gold sand or gravel. So far as known, no determined effort has been made in California to mine it, though the continued advance in its price and the occurrence of the metal in so many instances suggest the possible profit of such enterprise. Thirty years ago platinum was quoted at $4.50 an ounce; it steadily appreciated in price till "a corner" in '89 sent it up to $17.50 an ounce. That enormous figure of course occasioned tremendous activity, and three years ago the price went down to $7.50 an ounce. Since that there have been the usual rebounds and reactions that have affected everything made or mined in the world except gold; platinum is worth to-day about $10.50 an ounce, and it is not likely it will ever be less, as the practical supply seems limited while the demand must necessarily increase.

About ten years ago placer miners on the Similkameen river, British Columbia, were bothered with a stuff they called "white iron" and threw it away, as valueless. The MINING AND SCIENTIFIC PRESS investigated the subject, with the result that the apparently worthless by-product was found to be platinum. As usual it was in placer ground, but Prof. Dawson's explorations gave color to the assumption that the belt of diorite cut by the stream at the point where the platinum was found was the matrix of that metal, and that it would be found in place, while Blake, Van Cotta and others held that it was only an incideutal product from debris of serpentine or peridote. The Tulameen Improvement and Hydraulic Company was subsequently organized and active operations prosecuted, hydraulicking the placers of the Tulameen river with varying result. Of late that company has done little, but will resume active work this season. On the 12th of last month the corporation increased its capital stock to 500,000 shares, and is now about putting on a large force. The water of Eagle creek will be utilized, a flume and ditch carrying the water therefrom to the placer grounds. In this instance, as in all others except in Russia, gold is the principal inducement, the platinum output being but incidental. On the Demidoff estate and the government Goro-Blagodat district, in the Ural mountains, platinum is mined for itself alone. It is found in a ten-inch "streak" of sand resting upon a serpentine bedrock at a depth varying from ten to forty feet from the surface. A shaft is sunk to the bedrock, a drift run and the sand hoisted, fed with water into a revolving conical screen and sluiced. The industry furnishes employment to about 6000 men and women, the former earning about 60 cents, the latter 35 cents per day, this low wage being a part of "the European level" regarding which the California miner and manufacturer hear so much nowadays. The cost of washing these Ural platinum sands is about $16.75 per kilo of native metal, about forty cents per metric ton of sand washed. It is said that sand containing less than three grammes of platinum per ton cannot be profitably handled. The average is about four grammes per metric ton. On this there is a government tax of three per cent.

It is believed that the present annual consumption of platinum in electrical and other industries in this country approximates 50,000 ounces, nearly all of which is imported. It is found in connection with iridosmine in Butte, Plumas, Siskiyou, Trinity and Tuolumne counties in this State, and its great present value (about one-half that of gold) gives it proportional importance.

REGARDING the Mother Lode Power Co., referred to on page 229, one of the incorporators informs us that the capacity will be 3000 H. P., which can be furnished at about one-half the present rates.

That Amendment Again.

Immediately after the popular majority at the last State election for the constitutional amendment regarding alien ownership of real estate in California, came numerous inquiries to this paper from England regarding its effect upon foreign investments in mining property here. The question was answered, in effect that the intent of the law was all right; that subsequent Legislatures and State courts would undoubtedly construe it in accordance with such intent, and that the adoption of the amendment need not militate against any contemplated mining investment. The London *Times* and other leading British journals have given space to adverse comment on the new California law, which has had a bad effect on the proverbially timid capitalist. It is worth while to restate the facts. The new law vests in the State Legislature the power to legislate upon the real estate rights of alien residents. That is all there is to it. Of course, there is a possibility that future State Legislatures may do foolish things as well as many wise ones; but there is no probability that there will be any interference with aliens or foreigners, resident or non-resident, in acquiring, holding or disposing of mining properties in this State. The intent was and is to prevent foreign syndicates securing great areas of State land for speculative purposes, which has been done to the detrimeut of the commonwealth in other States of the Union. Its possible application to gold-mining properties was unthought of and is remote.

As to questions of policy, this paper does not believe that the gold-mining industry of the State is greatly concerned about the matter either way. While California is to-day the best field for foreign or domestic investment in gold mines, and while the State is always pleased to have the favorable attention of capitalists, native or alien—for money talks in all languages—yet the acquisition of valuable gold-producing property by other than residents of the State or Nation is not always a wholly desirable result, so far as the State is concerned, and the State has no apologies or excuses to make for evincing a desire to preserve its domain from the grasp of what in Europe is unfavorably known as "absentee ownership," with all that that implies. The foreigner who contemplates a mining proposition in this State may be assured that nothing has been nor is likely to be done to impair justly acquired title or interfere with possession or right of transfer.

THE critical care with which every line in this paper is read, and the general character of its circulation, have been strikingly illustrated by a slight slip in the wording of a recent advertisement, which unintentionally made an indirect statement that could not be borne out by strict construction of existing facts. Like a circle widening in the water for the first few days after the appearance of that particular issue of the paper came inquiry, comment and criticism from readers round about the city, then from the interior, and from States and Territories north, east and south, and later on from more remote readers. The work of acknowledging the receipt of so many missives from every part of the mining world was lightened by the consciousness that no statement or anuouncement in any department of the paper was overlooked by our thousands of weekly readers. The circumstance is recalled and emphasized by the receipt of nine letters this week regarding a six-line item that appeared on the first page of the issue of March 23rd, regarding the cost per ton of ore treated at the West Australia works of the Broken Hill Proprietary Co. Doubt had been expressed as to the accuracy of figures quoted, and each one of the nine had information and data on that subject, referring to the little item in question. We shall probably hear from that for the next ninety days. There are few places where mining is carried on that this paper does not reach, and it is believed that there is no paper which is read with more intelligent interest.

WITH considerable surprise *Industries and Iron* of London editorially notices that a contract "for 250 tons of wrought iron, inteuded for London, has been placed in Pittsburg, U. S. A., a firm in that city having succeeded in cutting out every home estimate for the order."

Concentrates.

THE *Register* says Butte county mines yield $1,000,000 annually.

PLACER COUNTY has contributed over $1000 to the State Miners' Fund.

THE Tacoma smelter is running almost exclusively on Kootenay ore.

IT is declared that the Trail Creek, B. C., ore carries a high percentage of nickel.

THE mill at the California mine, Washington, Nevada Co., started up again last week.

A TEN-STAMP MILL is to be put on A. V. McDowell's mine, the Columbian, at Baker City, Oregon.

THE Hall Mines Co. offer to put up a smelter at Nelson, B. C., if a $25,000 bonus is forthcoming.

THE new mining law for Arizona, will compel the mine locator to work his claim or abandon it.

AT the Hidden Treasure mine, Sunny South, Placer Co., 110 men are now employed—all white men.

THE Gold Bluff mine, near Downieville, was attached last week by an electric power company of this city.

IDAHO papers say the Tip Top mine at Silver City has been turned over to the owners of the Trade Dollar.

A ROLLER MILL is being put in at the Taylor mine, near Placerville, and will be ready to run next week.

THE old Dixie mill, on Lynx creek, Arizona, has been torn down, and a new ten-stamp mill is to be erected in its stead.

AFTER July 1, the charge in Montana for recording a quartz or placer claim will be $2 instead of $1 as at present.

DURING March there was shipped from Georgetown, Colorado, sixty-nine cars containing 1,726,300 pounds of ore.

THE Elsinore, Cal., *Press* acknowledges the receipt of "the report of the Southern California State Mining Bureau."

TEN stamps and two concentrators are to be added to the mill at the Gold Hill mine at Smith's Flat, Calaveras Co.

THE Colorado Legislature has passed a bill creating a State bureau of mines and appropriating $14,000 for its first year's expenses.

IT is again reported that the War Eagle mine, Trail Creek, B. C., has been sold to the Kansas City Smelter Company for $1,000,000.

AN explosion of fire-damp in the Blue Canyon coal mine, Lake Whatcom, Wash., last Monday afternoon, killed twenty-three men.

FIFTY men are employed at the Standard in the Cœur d'Alene, the ore being of a quality that gives a profit with silver at 63.

TO DATE 121 applications for hydraulic permits have been received by the U. S. Debris Commission. Eighty-six have been granted.

THE Standard Consolidated mine at Bodie is about to receive a new station and sinking pump made by the Dow Steam Pump Works.

THE Blewett mines and mill in the Peshastin, Wash., district, have been leased by former employes of the mining company, and will be started up May 1.

A CARLOAD of machinery for the Natlon Nickel Company is at Lovelock, Nevada, en route to the mines of the company in Churchill county. A smelter is to be built.

THE owners of the Similikameen, B. C., platinum mines claim that theirs is the second largest deposit of the mineral in the world. Active work is to be carried on this summer.

THE Turner Gold Mining Company has incorporated here: Directors—C. Roberts, E. P. Flint, J. Larue, R. T. Wurd and R. H. Campbell; capital stock, $100,000, all subscribed.

FOR the seven days ending March 29th the Finch Mining and Dredging Company at Lytton, B. C., took out 50¼ ounces of gold, valued at $909, the net profit on which was $700.

THE Nez Perces reservation in Idaho is to be opened to settlement on the first of next month. A rich gold mining country is said to be embraced within the borders of this tract.

IN answer to numerous inquiries it is again stated that there is no suspension of assessment work for 1895. The law has not been changed and the requirements are as hitherto.

THE Wadsworth Mining and Milling Company, of Washoe, has incorporated at Wadsworth, Nevada: capital stock $100,000. Trustees and incorporators: C. T. Washeim and W. R. Rich.

THE dividends paid by British Columbia mining companies in Spokane during the month of February aggregated $48,000; the Carihoo $8000, the Le Roi $8000, and the War Engle $32,000.

THE Altura Gold Mill and Mining Company of San Bernardino has increased its capital stock to $1,000,000. E. Otis, J. L. Campbell and T. W. Duckworth of San Bernardino are directors.

GEO. SENN, of this city, is about to open up the Baldwin mine, the Gracie, and Orleans, on Gold Flat, Nevada Co. Considerable heavy machinery will be put up and a large number of men employed.

The quantity of copper with which the Great Falls plant of the Boston & Montana Company is stocked amounts to about 7,000,000 pounds, which when reduced and put into merchantable shape is worth $407,000.

The latest new gold discovery is reported from Alberni, Vancouver's Island, where it is stated quartz taken from the Mountain Rose claim assayed as high as $900 to the ton, the lowest result being given at $40.

THE Denver *Record* says: "Placer miners are paid at San Pedro according to the luck they encounter in finding the pay streak. The wages generally are $1.50 and $2.00 per day, the miners receiving their pay every evening."

A COMPANY has been formed in Vancouver, B. C., to operate platinum hydraulic mining on the Tulameen river. Gold and platinum are said to occur in the gravel there in the proportion of two ounces of platinum to one of gold.

THE Daddy gold mine at Murry, in the Cœur d'Alene, has been closed down and the 55 men discharged, by reason of an injunction granted to the owners of the Yosemite, an adjoining claim. A new 10-stamp mill had just been finished.

THE Sacramento River Gold Mining and Milling Company has incorporated at Redding. Capital stock, $25,000. J. A. Kahny, T. A. Wilson, H. Frickinger, J. G. Burghacker of Redding, and E. Riehe of San Francisco are directors.

A SAN FRANCISCO physician claims great truth in the alleged discovery by M. Groussier of Paris of a scientific means of tracing the paternity of children who know not their own fathers, which becomes a local question of some interest.

THE Banning *Herald* reports that Mr. McHinney's mine, the "Desert Queen," is fully up to the first estimate. The discoverer also sends word that his statement, both as to richness and quantity of the ore, were not in the least exaggerated.

THE United States Debris Commission has begun suit in the case of the North Bloomfield Mining Company for alleged violation of its order in permitting the mine to be operated without constructing a dam in accordance with instructions.

THE United States Treasury Department is at last "going" to put into execution the provision of the new tariff law requiring silver and lead ores imported here to be assayed and sampled at the ports of entry, the principal one of which is El Paso, Texas.

THE Utica Mining Co. is sinking a shaft 1,000 feet deep on the Tryon property in the belief that the ore body found in the Stickle and Utica mines courses in that direction, and that at the depth of a thousand feet the same lode can be tapped.

THE California Debris Commission last Monday granted permits to the Grizzly Hill and the Dry Gulch, near Volcano, Amador Co. The application of the Rattlesnake Bar mine was refused, there being no satisfactory provisions for holding the tailings.

FOR the week ending March 28, 1895, Hillsboro, Sierra county, New Mexico, reports an output of 590 tons, gold ore; a total since January 1st, 1895, of 6360 tons. Most of the gold bullion shipments from that camp came to the Selby Smelting Works, here.

THE Gold Run Mining Company has incorporated at Carson, Nevada, to operate in Humboldt county, Nevada. The capital stock is $1,000,000, divided into 100,000 shares. The Directors are W. D. Tobey, T. R. Hofer, R. M. Clarke, H. Warren and Evan Williams.

THE Utica Water Co.'s reservoir, near Angel's Camp, burst last Thursday afternoon; the water in its rush toward the Mokelumne drowned an old man, Otto Lundt, living on Antonio creek. The dam cost about $45,000, and, it is thought, will have to be rebuilt.

THE African Gold Recovery Company (Limited) announces that 49,260 ounces of gold have been recovered at the Rand, and 8300 ounces in other districts; total, 57,560 ounces during February, by means of their MacArthur-Forrest cyanide process. The January total was 58,634 ounces.

MONTANA MEN have bought the Monita, Pilgrim and Surprise claims on Red Mountain, Trail Creek, B. C., for $60,000, the last payment to be made in eight months. These are extensions of the War Eagle, showing eight feet of ore. A local paper says 100 men will be employed within four months.

THE February output of the Witwatersrand district was 169,295 ounces, being less than the total January yield, which was less than the aggregate for the preceding month of December. London mining papers of the latest date received say this announcement "has stimulated business in the Kaffir market."

S. J. STADE was fatally injured in the south shaft of the Utica mine last Thursday. After endeavoring to "spit" the fuse of two holes to blast, he thought only one ignited and after the first charge exploded returned to light the other fuse. Just as he arrived at the spot the second charge exploded.

MANAGER STONEHAM, of the West Australian gold fields, writes that Coolgardie water can be had anywhere now for four pence per gallon. This is certainly a boon; now that it is known that water costs only eight cents a gallon the California rush to the Coolgardie gold fields will doubtless take the form of an exodus.

THE new law regarding the filing of any articles of incorporation provides that when certified by the Secretary of State, or by the County Clerk of the county where the original articles shall have been filed, they must be received in all the courts of this State, and other places, as prima facie evidence of the facts therein stated.

GEORGE THRASHER, for a Spokane company, is fitting up an outfit for mining on the Clearwater river, near Lewiston, Idaho, and has employed local rivermen to man bateaux to transport his freight to the upper river, twenty-miles above the Little North Fork, where the company has located an extensive bar of placer ground.

THE Philadelphia Gold and Copper Company, has incorporated in Salt Lake, Utah: capital stock $500,000. The property of the company consists of the J. C. Taylor Copper Plant, and other lode mining claims situated in Baker county, Or. J. C. Taylor is president, H. S. Stephens, vice-president; E. S. Sheets, secretary and treasurer.

DEER LODGE COUNTY, Montana, expects the liveliest year in prospecting in its history. Preparations on the part of many parties of gold seekers have already been made for extensive trips to the mountain ranges east, west and north to known mineral belts, and to those believed to exist in hitherto practically uninvestigated regions.

GOVERNOR RICKARDS of Montana is arranging for a conference to perfect an organization for an educational campaign on the silver question, to be held at Salt Lake City, May 15. He has sent a letter to the Governors of California, Oregon, Washington, Nevada, Idaho, Wyoming, Utah, Arizona, New Mexico and Colorado asking them to appoint three delegates to the Salt Lake conference.

IN the suit of the Eastern stockholders of the Bannister Mining Company at Butte, Montana, to cancel $100,000 first mortgage bonds on the ground that they were issued by fraud and in furtherance of a conspiracy among the Montana stockholders and trustees of the company, Judge McHatton of the district Court decided in favor of the Eastern parties and ordered the mortages to be surrendered, the bonds canceled, and the foreclosure sale perpetually enjoined and the repayment of $8000 in interest collected. The bonds were issued to President E. D. Bannister in payment of a mining claim sold to the company by him.

THE Montreal Hydraulic Gold Mining Company has incorporated at Carihoo, "to acquire the property of the Montreal and British Columbia Prospecting and Promoting Company, limited, certain placer mining properties in Cariboo and to operate the same." Capital stock, $250,000. Trustees, P. A. Peterson and J. Kennedy of Montreal, J. M. Browning, F. C. Innes and S. O. Richards of Vancouver.

A BILL passed by the last State Legislature and signed March 23rd amends Section 1416 of the Civil Code relative to notices of intention to divert water. Within sixty days after the notice is posted the claimant must begin work of excavation and pursue it diligently; but if a dam is advised by the California Debris Commission, sixty days are to be allowed after the completion of the dam in which to begin the excavation.

DURING the winter forty-eight men have been washing the banks of the Lardeau, B. C., for gold. Two men took out $3000 in dust and nuggets between them, and all have made good wages. Some of the nuggets taken out were worth $25 each. A large quantity of float, carrying gold, was found in the creek, and the miners will combine and prospect the mountains with the intention of discovering the ledge from whence came this quartz.

THIS is from the Amador *Ledger*: it is about one of California's big gold mines, not six months' travel on the other side of the globe, but a day's journey from this city: "$130,000 taken out of half a ton of rock is good pay ore, and not found every day: yet one day this week the Kennedy Mining Company hoisted a half ton of rock that assayed the above amount. So rich was the ore, it had to be taken to the sulphuret works to be refined; the mill could not handle it."

THE Tacoma Chamber of Commerce furnishes the following statement of Tacoma Smelting & Refining Co., for the month of March, 1895: Number of men employed, 63; pay roll, $4722.96; wood choppers and teams, $640—total, $5362.96; product, 2400 bars bullion weighing 247,317 lbs, copper matte weighing 56,700 lbs; contents—1572.50 ozs. gold at $20.67, $32,503.57; 22,370.25 ozs. silver at $0.63, $14,093.25; 257,274 lbs lead at $3.05 per cwt., $7846.85; 28,740 lbs copper at $0.09⅜, $2694.38—total, $57,138.05.

THE fourteenth annual report of the Hecla Consolidated Mining Company of Glendale, Montana, shows that for 1894 its gross receipts amounted to $146,769.13; it paid out for labor and all other expenses $290,596.35, leaving a net cash profit for the year of $156,172.73. On December 31, 1893, the cash surplus was $106,339.06, which, plus the net cash profit of 1894, is $262,511.84; deducting from this the eight dividends aggregating $120,000 paid in 1894, leaves a net cash surplus December 31, 1894, of $142,511.84.

D. W. BRUNTON, a prominent mining man of Aspen, Colorado, member of the firm of Taylor & Brunton, samplers, and manager of the Della S. mine, has had a preliminary trial before Justice A. P. Snow on the charge of maintaining a blacklist at the mine. A former foreman, Charles McHenry, produced the alleged blacklist in court, which contained the names of over 200 well-known Aspen miners. The Court held him to appear at the next term of District Court in the sum of $500. Considerable feeling exists in Aspen over the facts brought out at the trial.

A GEORGETOWN mining man tells of a queer mineral formation encountered in reopening an abandoned and closed drift in the Baxter mine. In the bottom of the drift is a drain. This drain, he says, was filled with a black paste-like substance which was gathered and put into ore sacks. An assay was made of it which gave a silver value of several hundred dollars per ton. He also tells the *Gazette* of the formation of a sulphide ore going on in the Gambetta lode. A number of years ago a long drift was driven on this property which exposed a continuous vein of zinc blende carrying about fifteen ozs. of silver to the ton. Over the exposed faces of this ore a thin crust of steel-gray mineral is forming which carries about fifty ounces of silver per ton.

ON the 26th ult. the Governor signed the recently-passed bill which amends section 1238, Code of Civil Procedure, relative to eminent domain. The right may be exercised for public uses in the following *new* instances: For "dams and poundings," for hyroads from highways to mines, mills, factories and buildings for operating machinery, or necessary to reach any property used for public purposes; for roads for transportation by traction engines or road locomotives; oil pipe lines; roads for logging or lumbering purposes; canals, reservoirs, dams ditches, flumes, aqueducts and pipes for supplying and storing water for the operation of machinery for the generating and transmission of electricity to mines, quarries, railroads, tramways, mills and factories; for power purposes, and light or heat, or mines, quarries or mills, or for cities and counties, villages and towns, together with lands, buildings and all other improvements in or upon which to erect, install, place, use or operate machinery for the purpose of generating and transmitting electricity for any of the purposes or uses above set forth; finally, electric light lines.

HERE is an (editorial) "prospectus" of a South African gold mining company clipped from the columns of London's ablest and most conservative mining paper: "The claims have been reported on by Mr. Pizzighelli, the Government surveyor. He states that a valuable water right has been secured from the Government in an adjacent stream, and goes with the property, and that there is enough power to drive a 10-stamp battery and accessories. A crushing of 70 tons of ore from the Royal Sheba ground is stated by him to have yielded over 13 dwts. to the ton. Taking it at the lowest estimate of 10 dwts. per ton, the following forecast may be regarded as moderate: Ten stamps will crush 40 tons per day, and working 300 days per year equals 12,000 tons, producing 6000 ounces of gold, or an average of 10 dwts. per ton, 6000 ounces of gold, at £3 17s.6d per ounce, £23,250; working expenses on 12,000 tons, at 12s per ton, £7200; gross profit per year, £16,050. This profit, after deducting £3550 for reasonable depreciation and management expenses, would leave £12,500 net profit—sufficient to pay a dividend of 25 per cent on the entire capital of the company." And those claims are far more moderate than many others at present published in the reading columns of reputable London journals.

Pocket Hunting in California.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS, M. E.

There are many pocket mines in Mariposa county, but some of the most noted of these are on the Mariposa estate and have not been worked for many years. Among these is the famous Oso mine, a short distance west of the village of Bear Valley, which vein is said to have produced $400,000 from a series of pockets found at the intersection of crevices. I visited the old workings in the hope of finding some evidence upon which to base an idea of the manner in which the rich deposits of this mine occurred, but the inaccessibility of the workings made this impossible. It was evident, however, that the openings were made along two series of veins, one running north and south, the other east and west.

The Mariposa mine, in the town of Mariposa, was extensively worked at one time, and has always been considered a pocket mine. How much the mine produced it is impossible to say. The known production reached hundreds of thousands of dollars, and it is generally believed, if not positively known, that an enormous amount of gold was stolen by miners working in the mine. Some of the specimens I have seen, said to have come from this mine, make it easy to believe that it would not be a hard matter for a miner to steal a hundred dollars without detection. As nearly as can be learned, the larger pockets found in the Mariposa occurred at or near points where the main vein branched, sending off shoots into the hanging or footwalls. The quartz is highly crystalline. The walls are black slate and diorite porphyrite.

The Missouri Gulch vein, located in the hills a mile northeast of the town of Mariposa, was a famous pocket vein, though not worked to any considerable depth. It was found by the placer miners in early days.

The French mine, on the north slope of Mount Bullion, about three miles northeast of Bear Valley, is a typical pocket mine, and has many openings along its course. Every gulch heading on the vein has been rich in gold. The vein is from one to four feet in width and shows a crystalline structure. Many very handsome quartz crystals have been found in this mine. The enclosing rock is diabase. The usual "gold seams" and "crossings" are said to occur, though I did not see any of the latter fissures.

On Bear Valley mountain is a vein called the Nevada. It strikes northwest and dips thirty degrees to the southwest. The gold occurs in pockets, and usually at a point in the vein where a mass of country rock (altered diabase) is enclosed in the vein. This type of pocket mine is not common in this section.

At a place known as the Bagley Field, northeast of Mariposa, I found a pocket vein in the granite which was unlike those of this region, though I have heard of similar occurrences elsewhere. The vein pitches to the westward, but the inclination is variable. It dips downward in a series of waves, the gold occurring on the flatter parts of the vein. These are called "floors." Neither "gold seams" nor "crossings" were observed in this place. The occurrence of gold, and ore deposits generally, on floors of this description is not uncommon. Just why this is so we can only theorize.

About eleven miles southeast of Coulterville, over the Buckthorn Mountain trail, is an interesting mine called the Black Bart. It is said to have produced a great many thousands of dollars at a very small expense. This mine is somewhat different from the ordinary pocket mine, but at the time I saw it the amount of development would hardly justify passing an opinion as to the persistence of the conditions under which the gold does occur. The formation is diabase altered into chloritic and talcose schist, which at a little distance from the vein becomes slaty or splintery diabase. Through the diabase has been intruded a later eruptive mass, which was found so thoroughly decomposed that positive identification of its character would be impossible, but its general appearance is that of a much decomposed felstone. The dike is from one to four feet in thickness. Immediately above it, and separating the felstone from the diabase, is a quartz vein from a seam to two feet in thickness. The quartz has a glassy appearance, is partly massive and partly crystallized. It may be well to remark here that quartz crystals in a vein is almost always an indication of bunchy pay or pockets in the Southern mines.

The first pocket found in the Black Bart produced $13,000, and was taken out within thirty feet of the surface. The men working this mine told me that they had learned from experience when a pocket was being approached. The indications were a highly mineralized condition of the quartz and the occurrence of a greenish scaly matter in the decomposed dike rock. The same conditions were observed in the Boudurant mine, five miles northwest of the Black Bart.

The dike rock of this mine is remarkably similar to that found in the Bonanza mine at Sonora, in Tuolumne county. The Black Bart vein is a well-defined fissure, and its course can be traced a long distance by the numerous old dumps made by earlier workers.

It is said of this interesting little mine that when a depth of thirty feet had been reached in the shaft the owners were compelled to seek assistance in carrying their work further. A partner was taken in, who put in some money on the showing already made. On the first shift he made a suggestion that the shaft be enlarged a little by breaking down a portion of the hanging-wall. One of the original partners thought the footwall would prove easier to work out, and accordingly the shot was put in the footwall. The first blast produced an unanticipated but happy result, for on going down after the blast to note its effect, the bottom of the hole was found glittering with gold. From that point the footwall was taken out to the surface, resulting in a cleanup of $13,000 in about two weeks.

Two men who prospected a flat on the summit of Buckthorn mountain for more than a month before finding pay, were repaid by taking out over $2000 within a month after finding the vein for which they had searched so long.

The story is told that Samuel L. Clemens (Mark Twain) was at one time a pocket hunter. He and his partners were not as fortunate in their search as some others. One day they had worked faithfully surfacing up a hillside and had actually located what they supposed to be the near vicinity of the coveted pocket. Heavy black clouds had overshadowed them in the meantime, and soon the great drops of rain began to fall, coming thicker and faster, and "Mark" and his pards dumped the dirt where they had found it and ran for shelter. Later they went home, and there Clemens wrote the renowned but ridiculous story that gave him his first fame—"The Jumping Frog of Calaveras." Soon after some Portuguese prospectors came upon the fresh work so hastily left by the Americans. The rain had washed away the dirt and gold was seen shining among the yellow earth. They kept the find secret for a long time, though it is said they took $7000 out with very little labor.

THE PORPHYRY BELT.

Beginning six or seven miles east of the town of Mariposa and extending in a northwesterly direction to Buckthorn Mountain, a distance of fifteen miles or more, is a great dike of eruptive rock of granitic type. This rock ranges in texture from felsite to granulite at the southern end and becomes somewhat coarser toward the northern end, where it often takes on the regular granitic habit, though still, for most part, fine grained.

Along the entire belt a large amount of development has been done, particularly on the southern end, where, for a distance of three miles or more, from a camp called Mono to another known as Colorado or "Colorow," it has been opened extensively both on the surface and at some points underground. I regret to say that the extremely bad condition of these old workings made it too dangerous to permit of a thorough inspection at all points, but wherever it was possible careful observation was made, and it appeared that the geological and mineralogical conditions were similar throughout this southern section of the belt. The largest and best exposures were found in a mine owned by George Lacy, near Colorado, and as the conditions found here are similar in all the others, a single description will suffice for all on this part of the lode. This belt is locally called and has heretofore been generally described and referred to as the "Talc mines." The rock forming the dike is not magnesian but quartzose and aluminous, being a decomposed granite of fine grain.

The dike varies from four to about thirty feet in width, and in a few places it was observed that it had sent branches out into the country rock—a fine, smooth slate. The dike strikes northwest and stands nearly perpendicular. The only variation in dip was the apparent change due to the swelling or pinching of the dike material. It conforms, as nearly as could be ascertained, to the general strike of the slates.

The entire mass of the dike rock is shattered and seamed in every direction. Many of the seams are filled with infiltrated veinlets of quartz.

The most prominent of these quartz-filled seams or veins is a series which crosses the dike from wall to wall, and not extending beyond the limits of the dike rock itself. These seams are from an inch to a foot or more in thickness. The seams occur with quite noticeable regularity, lying nearly flat, about four to six feet apart. The seams are filled with highly crystallized quartz, silicious limonite, black manganese oxide and decomposed dike material. Many of the quartz crystals are of great beauty and some of them of considerable size—four to six inches in diameter. I saw two crystals of large size at Colorado containing pretty inclusions of moss-like, greenish material, probably chlorite.

In the northern portion of this mine the strike of these quartz seams is northeasterly, nearly at right angles to the strike of the dike. In this portion of the mine the gold, which always occurs in pockets, is found near the east wall, either imbedded in the quartz or lying between the quartz and the dike rock.

In the southern portion of the mine the strike of the seams is due east and west, the dip seventy-seven degrees north. Strange to say, here the gold is found under similar conditions on the west side of the dike, directly contrary to the position it was found to occupy at the northern end. I was unable to give sufficient time to a study of the conditions to find any reason for this peculiar freak of gold deposit. A complete, careful study of the conditions under which pockets occur here would be most interesting.

The development of these mines is, as has been stated, largely superficial—that is, by a series of open excavations, made along the surface and upper portions of the dike. In the Lacy mine alone there has been removed 100,000 tons of rock, and mostly by one man—the owner. The open cut is 600 feet long, from 20 to 60 feet wide, and at one place 100 feet wide (due to a slide of the wall rocks into the pit).

The pockets are carefully searched for at the points indicated. The waste resulting from a season's work, consisting of broken masses of dike rock, quartz and slips from the walls, is allowed to accumulate in the pit, and the whole is sluiced out by the hydraulic method when sufficient water is available. Fortunately, there is abundant dump, as the mines are a thousand feet or more above the canyon of the Merced river.

The gold obtained is coarse and occurs in forms of great beauty, forming pieces suitable for jewelry which the most expert goldsmith would be puzzled to duplicate. It usually has a crystallized appearance and frequently retains what seems to be the impression of the matrix of quartz in which it was formed. There are delicate markings and indescribable flutings seen under a lens not noticed at a casual inspection. Many of these pieces are sold at a price exceeding their intrinsic value.

The quartz contains no fine gold as far as known and is not saved; all the gold recovered in working these mines is readily seen with the unaided eye and picked out by hand.

Ten or twelve miles northwest of the Lacy mine, on the north side of Merced river, is found a series of these mines on the same dike. The open cuts can be seen for miles in bold relief among the dark green chimisal brush which covers the otherwise barren hills.

The mines most extensively opened on this portion of the belt are known as the Defiance and Harrison. The dike rock in this section is from thirty to more than 100 feet wide. The rock is harder and more firm than at Colorado, but still greatly altered. The quartz veins crossing the dike lie mostly more nearly horizontal, and gold is found on both sides of the dike. The country rock enclosing the dike is similar to that south of the river, though rather more shaly. The dip of the dike is from seventy-five to eighty degrees. These pockets have undoubtedly enriched the numerous gulches heading up in the vicinity of the dike. Solomon's and Flyaway gulches were famous placer fields.

The scarcity of water on these high hills has proven a great drawback in working these mines in the past. The belt is fully fifteen miles in length and not over seven miles of it has been prospected, and even in the largest mines the amount of underground development is comparatively small. It would appear that this might prove a field for the pocket hunter to exercise his skill and perseverance.

Placer County Mines.

TO THE EDITOR:—The Blue Canyon placer gravel mine, owned by S. C. Jordan of Dutch Flat, has lately been bonded to W. T. Jackson of Sacramento and Prof. F. J. Kimball, et al., for three years. The parties who have bonded it propose to run a tunnel into the mine the length of 2800 feet, which will tap the channel.

The Shady Run quartz mine, also owned by Mr. Jordan, located five miles east of Dutch Flat, has been bonded to New York capitalists for a period of ten months. This new company propose to put up a mill and thoroughly develop this mine. This mine, the ore of which runs fifteen per cent of gold, has two distinct ledges; one is a foot wide and 100 feet deep; the other is six feet wide and sixty feet deep. Mr. Jordan feels confident that with these new companies the output will increase and prove a profitable investment both for the new companies and himself.

Mr. E. Mallons, who owns the Golden Shaft mine, near the edge of Dutch Flat, which has a shaft down already ninety feet, intends to at once go ahead with developing his mine by running side drifts and erecting an eight-stamp mill thereon. The mill is on the road and, as soon as the weather permits, the work will be pushed. It is a cement gravel mine, and Mr. Mallons estimates the total expense of getting ready will be $10,000, two-thirds of which amount has been expended. It is expected to pay from $3 to $4 per ton. The skip process self-dumping apparatus is adopted.

W. S. Garrett, superintendent of the Polar Star gravel mine at Dutch Flat, states that ground sluicing and hydraulicking was commenced on the 1st inst., and is to continue through the summer. They have employed thirty men and anticipate a

prosperous season. The claim contains 107 acres and they are washing on the bed rock with a 150-foot bank. Everything has been fitted up to meet the demands of the business.

At Iowa Hill it is claimed that over $3,000,000 in gold has been taken out just north of and adjoining the town, and more is left for the next generation. A Mr. Brown, who had a claim near Iowa Hill in 1854 that paid $10 to the pan, returned—after an absence of forty-one years—a few weeks ago, and found his claim just as he left it, minus the $10 per pan.

Miners looking for work and prospectors looking for good paying locations, are constantly met on the road, going to and fro, as in the days of old, by yours truly, TRAVELER.

Development of Mines.

Demands for Locations — Foreign Cut in Wages — Present System of Business, Etc.

TO THE EDITOR:—On a recent trip in the mining districts several things were forcibly impressed upon my mind, and one is the utterly absurd values placed on mining prospects that are in many instances mere locations and in others but holes of 10, 15 or 30 feet deep.

It should be borne in mind that such senseless demands are simply causing property to lie undeveloped and possibly unproductive, to the detriment of both the owner and the community where located. Many act on the principle that "the fools are not all dead yet," and that some one will come along who will be charmed with the idea that there is no "hole in the ground" and make the purchase, while the fact is—in mining ventures—the fools are all dead, and unreasonable demands make poor business.

When it comes to development of locations, the "prospecting" miner cannot put in his time to a better purpose than properly opening his supposed mine, and develop thereby a value which will give some guarantee for a reasonable amount to be paid. A well-opened mine, by the expenditure of considerable labor, is really more salable at a high price than a less developed one at a low figure. It is to be hoped for the business of the State that the "prospecting" miner will make developments on his valuable property before offering the same for sale; if unable to do so, he would benefit himself and the community by offering somebody one-half for a certain amount of development work. How many "prospectors" are there who have claims that they have held for years with nothing of value done on them! There should be an end to such a system. It does not benefit any individual. Work benefits the entire people, and now that the mining interest is "looking up," every undeveloped-mine owner should watch the chance for making active such "prospects" as he may have.

That there is great injury inflicted on the community of every town and county by this "dog-in-the-manger" policy as to locations, every one certainly knows; the persons to correct it are the claimants themselves, and the way is by inaugurating a more liberal and active policy.

While I am on the question of development, I want to say that the American miner does not as yet, except in a very few instances, show the same amount of mining dash and venture as the English mine operator. I mean in the way of laying out a large work, requiring vast capital before any returns are to be expected. The American miner moves as though having a great doubt, the Englishman with confidence and a knowledge that development of great depth will bring success, while scratching about the surface simply scatters money and often produces failures. I am aware that we have in California deep workings by American enterprise, but these are mainly the result of the large output of rich ore they keep going for. In South Africa at this time several companies are expending from one million to one and a half million of dollars on development and plant before expecting to have one dollar of returns. That is mining with confidence. I do not mean to say that this is desirable at all times, but I do say that we on this coast want to enlarge our ideas as to development and to take up the pursuit of mining with more confidence, and instead of going into development work by piecemeal, start to open our mines to a depth of a thousand feet, considering this the requisite for determining as to the real value of any lode having favorable features about it. Every prepossessing mineral-bearing lode at one point or another of a thousand-foot development is very likely to produce more value than the entire cost of such a development.

Of course, this takes capital as well as confidence. Here in California we have unbounded wealth in our mines and we do not appreciate the gift. Our business men, with a very few exceptions, do not encourage mining enterprises or in any way strive to build up an industry that has more real wealth and is of more benefit to the whole people than any one single industry. Grains, fruits and wines do not add the volume to the world's capital that mining does. Within the past ten years there has been invested in South Africa over $1,000,000,000 of European capital, the greater part of it going there in the past six years. This vast investment in mines has been giving an output of from $20,000,000 to $30,000,000 per annum. The amount of money Europeans have put into mining enterprises in South Africa, Australia and New Zealand is beyond all calculation, and here in this great gold-bearing State, with double the advantages in every sense, we have not the pluck nor enterprise to produce even $13,000,000; in fact, Wells, Fargo & Co.'s estimate for 1894 was only $10,690,646.

If we have a good mining property the first thing we do is to sell our chances to some foreign investor, who seldom buys bad properties. This done, the purchaser, in very many instances, on taking possession looks around and commences work at once, ostracizing the Americans and putting in their stead men of his own nationality; if he is English he puts in Englishmen, if French then Frenchmen, and so on through all nationalities. This is natural, but the American does not do it. The main object in doing so is to reduce wages, which is too often done. I have in mind an English company who no sooner took possession of a property than the miners' wages were cut from $50 a month to $40, and general labor from $1.25 per day to $1 and board. By such operations all outlays for labor go into the hands of a poor foreign element, who are kept poor by poor reward for their labor. This reducing of wages to a pittance insures better profit for the company, all of which when made is at once shipped out of the country. The employing of special nationalities in preference to Americans is not so detrimental to the general interest, for these laborers are citizens and, through necessity, must distribute their gains. For the best interests of our State, however, we should operate and own our mines, and thus hold all the product for the benefit of our people. Californians do a great deal of talking as to what ought to be done in order to make more general prosperity for the masses but, as a business community, will not maintain it. From a former liberal policy of business we have drifted too much into the "cent-per-cent" channel of thought instead of into a broad industrial one, which in time would afford every man employment and keep our money at home.

Recently we subscribed over $2,500,000 for the San Joaquin railroad, and at once gave a contract for rails, etc., which will carry away at least $2,000,000 of the people's money, when the whole outfit should have been made in San Francisco. One may say the outfit could not be made here for the same money. There was no effort to see if all the work could be done here. There was no conference of capital and labor to test this question. Suppose it costs 10% more, would not we all be better off by distributing this labor and capital among our own people? The money would then be here for some other operation. We have the location and foundation for one of the wealthiest communities on the face of the globe—a grand field for men of brains, enterprise and capital to work in—and where are we?

Is there not a wrong system in operation? Our manufacturing establishments are virtually idle and yet we are building and buying all the time, enriching other States by paying away our gold instead of planning to keep it at home. This is our way of doing business, but ought we not change it? What wants to be done for the good of all is to get every prospective mine opened as a producer. Keep the resources of every developed mine here; this means more money and more employment of our labor, and, in connection with this, have all our wants supplied by home production—in other words, get out and put into circulation more money and keep it here in general circulation. ALMARIN B. PAUL.

San Francisco, April 3, '95.

Mother Lode Power Company.

The Mother Lode Power Company has been organized to furnish electric power to the mines between the Mokelumne river and Amador City. They own a water right, taking the water from a point above Tripp's mill and will carry it down the river several miles, where a generating station will be put in. Here a plant will be installed, supplied with the latest types of multiphase electric machinery, similar to that now being put in at the celebrated Niagara Falls station.

From this point lines will be run so as to be in position to furnish power to a large number of mines. The capacity of the plant will be 1000-horse power, and it is intended to have things ready to furnish this amount before the next winter. Bonds are now being subscribed, and active operations will begin in a few days. The entire installation will be in the hands of the firm of Hasson & Hunt of San Francisco, who had entire charge of the installation and operation of the magnificent plant at the Midwinter Fair.—Amador Republican.

A LONDON cable says: Practical advantage has already been taken by the British postal authorities of the new method of telegraphy without wires. The cable from Scotland to the Isle of Mull was broken for a week, and during that time the inhabitants remained in electric communication with the mainland by means of the induction apparatus. The distance from the mainland is two miles. There were already wires along the island coast. A parallel wire was erected on the coast of the mainland, and messages sent over it were received by telephone connected with the wire on the island, and vice versa.

Description of the Gold Belt of California.*

Written by H. W. TURNER.

The gold belt of California includes that portion of the Sierra Nevada lying between the parallels of 37° 30 and 40°. This area is bounded on the east by the great basin and on the west by the great valley of California, comprising about 17,000 square miles. The Sierra Nevada here forms a single range, sloping somewhat abruptly toward the great basin and gradually toward the great valley of California. Within this area lie the chief gold deposits of the State, though by no means all of the area is auriferous. At the northern limit the deposits are scattered over nearly the entire width of the range, while to the south the productive region narrows to small dimensions. The mass of the range south of Alpine county is comparatively barren. North of the 40th parallel the range is probably not without deposits, but the country is flooded with lavas which effectually bury them.

The rocks of the Sierra Nevada are of many kinds and occur in very complex associations. They have been formed in part by deposition beneath the sea, and in part by intrusion as igneous masses, as well as by eruption from volcanoes, and portions of them have been subsequently metamorphosed.

The southern portion of the range is composed of granite. The central and northern part, west of longitude 120° 30', consists prevailingly of schists, which have been produced by intense metamorphism of both ancient sediments and igneous rocks, and it is chiefly but not solely in these schists that the auriferous quartz veins occur. The trend of the bands of altered sediments and of the schistose structure is generally from northwest to southeast, parallel to the trend of the range, but great masses of granite and other igneous rocks have been intruded among these schists, forming irregular bodies which interrupt the regular structure and which are generally bordered each by a zone of greater metamorphism. These schists, with their associated igneous masses, form the older of two great groups of rocks recognized in the Sierra Nevada. This group is generally called the bedrock series.

Along the western base of the Sierra occur beds of sandstone and clay, some of which contain thin coal seams. These are much younger than the mass of the range and have not shared the metamorphism of the older rocks. They dip gently westward beneath the later deposits, which were spread in the waters of a shallow bay occupying the valley of California and portions of which have been buried beneath recent river alluvium.

Streams flowing down the western slope of the Sierra in the past distributed another formation of great importance—the auriferous gravels. The valleys of these streams served also as channels for the descent of lavas which poured out from volcanoes near the summit. Occupying the valleys, the lavas buried the gold-bearing gravels and forced the streams to seek new channels. These have been worn down below the levels of the old valleys, and the lava beds, with the gravels which they protect, have been isolated on the summits of ridges. Thus the auriferous gravels are preserved in association with lavas along lines which descend from northeast toward southwest, across the trend of the range. The nearly horizontal strata, together with the auriferous gravels and later lavas, constitute the second group of rocks recognized in the Sierra Nevada. Compared with the first group—the bedrock series—these may be called the superjacent series.

The history of the Sierra Nevada, even so far as it is recorded in the rocks, has not yet been fully made out, but the events of certain epochs are recognized, and these may be stated in a brief summary in the order in which they occurred.

THE PALEOZOIC ERA.

During the Paleozoic era, which includes the periods from the end of the Algonkian to the end of the Carboniferous, the State of Nevada west of longitude 117° 30' appears to have been dry land of unknown elevation. This land probably extended westward into the present State of California and included part of the area now occupied by the Sierra Nevada. Its western shore was apparently somewhat west of the present crest, and the sea extending westward received Paleozoic sediments which now constitute a large part of the central portion of the range.

At the close of the Carboniferous the Paleozoic land area of western Nevada subsided, and during a portion or all of the Juratrias period it was at least partly covered by the sea. At the close of the Juratrias, according to the latest paleontological determinations, the Sierra Nevada was upheaved as a great mountain range, the disturbance being accompanied by the intrusion of large amounts of granite.

The auriferous slate series comprises all of the sedimentary rocks that entered into the composition of this old range of Juratrias time. Formations representing the Algonkian and all of the Paleozoic and

*From the Geologic Atlas of the U. S.

Juratrias may therefore form part of the auriferous slate series.

Fossils of Carboniferous age have been found in a number of places, and the presence of silurian beds at the northeast base of the range has been determined. A conglomerate occurs in the foothills of Amador and Calaveras counties, interbedded with slates containing carboniferous limestone; this conglomerate is therefore presumably of Carboniferous age. The conglomerate is evidence of a shore, since it contains pebbles of quartzite, diabase and hornblende-porphyrite, which have been rounded by the action of waves. The presence of igneous pebbles in the conglomerate shows that volcanic eruptions began at a very early date in the formation of the range, for the hornblende-porphyrite pebbles represent lavas similar to the hornblende-andesites of later age.

The Paleozoic sediments of the gold belt consist of quartzite, mica-schist and clay-slate, with limestone lenses. Rounded crinoid stems, *Lithostrotion*, *Fusulina*, *Clisiophyllum*, *Spirifera*, and other genera have been found, chiefly in the limestone, and indicate that the age of the rocks is Carboniferous. The Paleozoic sediments are finely exposed in Calaveras county, and on the gold belt sheets they will be designated the Calaveras formation. It is probable that some areas mapped as Calaveras may contain strata earlier or later than the Carboniferous.

During an epoch of upheaval some time after the close of the Carboniferous period, these sedimentary strata were raised, forming part of a mountain range. The beds were folded and compressed, and thus rendered schistose. Granite and other igneous rocks were intruded among them, and they assumed somewhat the relations which they now exhibit in the Sierra Nevada. But those masses which now form the surface were then deeply buried in the foundations of the range. They have been brought to the present surface by subsequent uplifts and prolonged erosion.

JURATRIAS PERIOD.

The areas of land and sea which existed during the earlier part of this period are scarcely known. Strata showing the former presence of the sea have been recognized in the southeastern portion of the range at Mineral King, where the sediments are imbedded in eruptive granite, and at Sailor Canyon, a tributary of American river. Rocks of this age occur generally throughout the great basin and the Rocky mountains, but the interior sea or archipelago in which they were deposited was apparently separated from the Pacific by a land mass stretching the length of the Sierra Nevada. This land probably originated in the upheaval above referred to, some time after the close of the Carboniferous, and toward the end of the Juratrias period its area became so extensive that the waters of the Pacific seem to have been completely separated from the interior seas. This conclusion is based upon the fact that fossils of Jurassic age in California, so far as known, have closer relations with those of Russia than with those of eastern America.

The genus *Aucella*, whose shells occur in Russia, flourish on the Pacific coast until well into the Cretaceous, and is distributed from Alaska to Mexico. In the Juratrias strata of California it is associated with ammonites of the genera *Perisphinetes*, *Cardioceras* and *Amaltheus*, which are closely related to forms of the European Upper Jurassic.

The strata in which these fossils occur are prevailingly clay slates, which are locally sandy and contain pebbles of rocks from the Calaveras formation. Thus it is evident that they were deposited near the shore of a land composed of more ancient schists, and the generally fine character of the sediment shows that the land which occupied the area of the Sierra Nevada cannot have been very mountainous. These strata now occur in two narrow bands along the western base of the range, and are called the Mariposa formation, from the fact that they are well exposed near Mariposa.

Soon after the Mariposa formation had been deposited the region underwent uplift and compression. The result of uplift was the development of a mountain range along the line of the Sierra Nevada. The Coast Range also was probably raised at this time. The action of the forces was such as to turn the Mariposa strata into a vertical position, shattering the rock and deforming it, and producing some metamorphism. The clay shales now have a slaty structure, produced by pressure, which appears to coincide in most cases with the bedding. It was a time of intense eruptive activity. The Mariposa beds were injected with granite, and vast masses of diabase, associated with other basic igneous rocks, date from this time. There is evidence that igneous rocks were intruded in varying quantities at different times, but that the intrusion of the great mass of the igneous rocks accompanied or immediately followed the upheavals is reasonably certain.

The Mariposa beds carry numerous gold veins, the most important group of which constitutes the famous "Mother lode." It is believed that most of the gold veins were formed after this upheaval, and as a consequence of it, occupying fissures opened during the uplift.

The disturbance following the deposition of the Mariposa beds was the last of the movements which produced the vertical arrangement of the auriferous slate series. The strata of succeeding epochs are sediments and tuffs. Lying nearly horizontal or at low angles, they prove that since they were accumulated the rock mass of the Sierra Nevada has not undergone much compression. But the fact that they now occur high above sea level is evidence that the range has undergone elevation in more recent time.

CRETACEOUS PERIOD.

By the close of the Juratrias the interior sea of North America had receded from the eastern base of the Sierra Nevada eastward beyond the Rocky mountains. From the western part of the continent the waters of the Pacific had retired in consequence of the Juratrias uplift. The valley of California was then partly under water, and the Coast Ranges seem to have been represented by a group of islands, but during the later Cretaceous the region subsided and the sea substantially overflowed it. Through gradual changes of level the areas of deposition of marine sediments were shifted during the Cretaceous and Neocene periods, and late in the Neocene the sea once more retreated west of the Coast Ranges. The deposits laid down during this last occupation of the valley of California belong to the superjacent series.

The advance of the sea spread a conglomerate over the eastern part of the valley in later Cretaceous time, and sandstone and shale were subsequently deposited. This formation is well developed near Chico, and at Folsom, on the Sacramento sheet. It has been called the Chico formation.

EOCENE PERIOD.

In consequence of slow changes of level without marked disturbance of the Chico formation, a later deposit formed, differing from it somewhat in extent and character. The formation has been called the Tejon (Tay-hone). It appears in the gold-belt region at the Marysville Buttes, aud it is extensively developed in the southern and western portions of the valley of California.

NEOCENE PERIOD.

The Miocene and Pliocene ages, forming the later part of the Tertiary era, have in this atlas been united under the name of the Neocene period. During the whole of the Neocene the great valley of California seems to have been under water, forming a gulf connected with the sea by one or more sounds across the Coast Ranges. Along the eastern side of this gulf was deposited during the earlier part of the Neocene period a series of clays and sands to which the name Ione formation has been given. It follows the Tejon, and appears to have been laid down in sensible conformity to it. Marine deposits of the age of the Ione formation are known within the gold belt only in the Marysville Buttes. Along the eastern shore of the gulf the Sierra Nevada, at least south of the 40th parallel, during the whole of the Neocene, and probably also during the Eocene and latest Cretaceous, formed a land area drained by numerous rivers. The shore line at its highest position was several huudred feet above the present level of the sea, but it may have fluctuated somewhat during the Neocene period. The Ione formation appears along the shore line as blackish-water deposits of clays and sands, and frequently it contains beds of lignite.

The drainage system during the Neocene had its sources near the modern crest of the range, but the channels by no meaus coincided with those of the present time. The auriferous gravels for the most part accumulated in the beds of these Tertiary rivers, the gold being derived from the croppings of veins. Such gravels could accumulate only where the slope of the channel aud the volume of water were sufficient to remove the silt while allowing the coarser or heavier masses to sink to the bottom with the gold.

The climate of the late Neocene was warm and humid, much moister thanit would have been if the great valley had been above water, and erosion was correspondingly rapid.

A mountain-building disturbance occurred duriug the Neocene period. This was caused by pressure acting from the SSW. toward the NNE. with a downward inclination. One effect of this pressure was to induce movements on a network of fissures, often of striking regularity, intersecting large portions of the range. It is not improbable that this fissure system originated at this time, but there are fissures of greater age. This disturbance also initiated an epoch of volcanic activity accompanied by floods of lavas† consisting of rhyolite, andesite and basalt, which continued to the end of the Neocene. These lavas occupy small and scattered areas to the south, increasing in volume to the north until, north of the 40th parallel, they cover almost the entire country. They were extruded mainly along the crest of the range, and often followed fissures belouging to the system mentioned above. The recurrent movements on the fissures were probably accompanied by an increase in the development of the fissure system. An addition to the gold deposits of the range attended this period of volcanic activity.

When the lavas burst out they flowed down the river channels. Sometimes they were not sufficient to fill the streams, and are now represented by layers of "pipe clay" or similar beds in the gravels. These minor flows were chiefly rhyolite. The later andesitic and basalt eruptions were of great volume, and for the most part completely choked the channels into which they flowed. The rivers were thus obliged to seek new channels—substantially those in which they now flow.

Fossil leaves have been found in the pipe clay and in other fine sediments at numerous points. Magnolias, laurels, figs, poplars and oaks are represented. The general facies of the flora is thought to indicate a low elevation, and has been compared with that of the flora of the South Atlantic coast of today.

PLEISTOCENE PERIOD.

During Cretaceous and Tertiary time the older Sierra Nevada had been reduced by erosion to a range with gentle slopes. An elevation of the range doubtless attended the Neocene disturbance above referred to, and minor dislocations probably recurred at intervals; but at the close of the Tertiary a greater uplift occurred, which was accompanied by the formation of normal faults. These were widely distributed throughout the range, particularly along the eastern escarpment, where they form a well-marked zone to the west of Mono lake and Owen lake. As a consequence of this elevation the streams, having greater fall, cut new and deep canyons in the hard but shattered base of the pre-existing mountains.

A period of considerable duration elapsed between the emission of the lava flows which displaced many of the rivers and the time at which the higher Sierra was covered by glaciers. In the interval most of the deep canyons of the range were cut out. Such, for example, are the Yosemite valley on the Merced river, the great canyon of the Tuolumne, and the canyon of the Mokelumne. The erosion of these gorges was often facilitated by the fissure system referred to above, and many of the rivers of the range follow one or other set of parallel fissures for a long distance.

It is a question at what point the limit between the Neocene and Pleistocene should be drawn. It has become usual to regard the beginning of the Glacial epoch in eastern United States as the close of the Neocene. If it could be shown that the glaciation of the Sierra was coeval with that of northeastern America, a corresponding division would be adopted. It is believed, however, that glaciation was much later in California than in New England, and that the great andesitic flows mark the close of the Neocene.

The Sierra, from an elevation of about 5000 feet upward, was long buried under ice. The ice did not to any noticeable extent erode the solid rock in the area which it covered, although it removed enormous amounts of loose material. Its seems rather to have protected it from erosion while intensifying erosion at the lower elevations, just as would a lava cap. Small glaciers still exist in the Sierra.

IGNEOUS ROCKS.

Rocks of igneous origin form a considerable part of the Sierra Nevada. The most abundant igneous rock in the Sierra Nevada is granite, this term embracing both granodiorite and true granites. Rocks of the granitic series are believed to have consolidated under great pressure and to have been largely intruded into overlying formations at the time of great upheavals. Thus granite is a deep-seated rock, and is exposed only after great erosion has taken place.

The rocks called diabase and augite-porphyrite on the gold belt maps are not always intrusive, but to some extent they represent surface lavas and correspond to modern basalt and augite-andesites. In like manner, some of the hornblende-porphyrites correspond to hornblende-andesites.

GLOSSARY OF ROCK NAMES.

The sense in which the names applied to igneous rocks have been employed by geologists has varied and is likely to continue to vary. The sense in which the names are employed in this article is as follows:

Gabbro.—A granular intrusive rock consisting principally of diallage or allied monoclinic pyroxene, or a rhombic pyroxene, together with soda-lime and lime feldspars.

Gabbro-diorite.—A term used to indicate areas of gabbro coutaining primary and secondary hornblende and areas containing intimate mixtures of gabbro and diorite.

Pyroxenite.—A granular intrusive rock comprised principally of pyroxene.

Peridotite.—A granular intrusive rock generally composed principally of olivine and pyroxene, frequently of olivine alone.

Diorite.—A granular intrusive rock consistiug principally of soda-lime feldspar and hornblende.

Serpentine.—A rock composed of the mineral serpentine, and often containing unaltered remains of feldspar, pyroxene or olivine. Serpentine is fre-

†The term "lavas" is here used to include not only such material as issued from volcanic vents in a nearly anhydrous condition and at a very high temperature, but also tuff-flows and mud-flows, and, in short, all fluid or semi-fluid effusive volcanic products.

quently a decomposition product of rocks of the peridotite and pyroxenite series.

Granodiorite (quartz-mica-diorite).—A granular intrusive rock having the habitus of granite and carrying feldspar, quartz, biotite and hornblende. The soda-lime feldspars are usually considerably and to a variable extent in excess of the alkali feldspars. This granitic rock might be called quartz-mica-diorite, but this term, besides being awkward, does not sufficiently suggest its close relationship with granite; it has therefore been decided to name it "granodiorite."

Granite-porphyry.—A granite with large porphyritic potash feldspars.

Amphibolite, amphibolite-schist.—A massive or schistose rock composed principally of green hornblende, with smaller amounts of quartz, feldspar, epidote and chlorite, and usually derived by dynamo-metamorphic processes from diabase and other basic igneous rocks.

Diabase.—An intrusive or effusive rock composed of augite and soda-lime feldspar. The augite is often partly or wholly converted into green, fibrous hornblende or uralite.

Augite-porphyrite.—A more or less fine-grained rock of the diabase series, with porphyritic crystals of augite and sometimes soda-lime feldspars.

Hornblende-porphyrite.—An intrusive or effusive porphyritic rock consisting of soda-lime feldspars and brown hornblende in a fine groundmass.

Quartz-porphyrite.—An intrusive or effusive porphyritic rock consisting of quartz and soda-lime feldspar, together with a small amount of hornblende or biotite. It is connected by transitions with granodiorite and with the following:

Quartz-augite-porphyrite.—This the same as the above except that it contains augite. It is connected by transitions with augite-porphyrites and with quartz-porphyrites.

Quartz-porphyry.—An intrusive or effusive porphyritic rock, which differs from quartz-porphyrite in containing alkali feldspars in excess of soda-lime feldspars.

Rhyolite.—An effusive rock of Tertiary or later age. The essential constituents are alkali feldspars and quartz, usually with a small amount of biotite or hornbleude in a groundmass, often glassy.

Andesite.—An effusive porphyritic rock of Tertiary or later age. The essential constituents are soda-lime feldspars and ferromagnesian silicates. The silica is usually above fifty-six per cent.

Basalt.—An effusive rock of Tertiary or later age, containing soda-lime feldspars, much pyroxene, and usually olivine. The silica content is less than fifty-six per cent. It is also distinguished from andesite by its structure.

A Satisfactory Test.

One of the 5000-horse power double inverted turbine wheels and the 5000 electrical generator at Niagara Falls were tested last Saturday in the presence of the officers and stockholders of the Construction and Power Company. The No. 1 turbine wheel was used. The machine was started at seventeen revolutions per minute, and increased gradually to thirty-two revolutions. To generate 5000-horse power 250 revolutions must be reached. The mass of steel and iron comprising the wheel, shaft and dynamo, estimated at seventy-five tons, was held poised on the bearings by the weight of the water which strikes the turbines from below. The huge mass bobbed up and down like a cork on the water. There was no hitch or jar in the running of the turbine. The electric generator was not connected with the armature, and no electricity was provided. The secretary states that the results were wholly satisfactory.

THE Gates Iron Works, of Chicago, which for over fifty years has been located between Madison and Washington streets, will move this month, and after May 1st will occupy the new works fronting on Elston avenue, Bloomingdale road, Redfield and Stein streets, the office address being 690 Elston avenue. The branch office will be Room 1205, Stock Exchange Building, La Salle and Washington streets.

Personal.

W. C. MINEAR is in charge of the operations at the Hite mine, Mariposa Co.

STATE MINERALOGIST CRAWFORD has returned from El Dorado county.

W. S. CHAPMAN is in Mariposa Co. arranging for work on the Vanderhilt mine.

T. A. RICKARD is now State Geologist of Colorado—a most excellent appointment.

PAUL SCHULTZE has resigned his position of general land agent of the Northern Pacific at Tacoma, Wash.

MR. AND MRS. JNO. HAYS HAMMOND sailed from London on the 30th ult. for Johanneshurg, where they will permanently reside.

PROF. H. V. WINCHELL, accompanied by F. F. Sharpless, is examining the auriferous black sands on the Coos county, Oregon, beach.

T. B. WILCOX, of Portland, Or., has been elected vice-president of the Washington & Columbia River Road. He succeeds C. B. Wright Jr.

CHARLES D. WALCOTT of the United States Geological Survey has had conferred upon him the Bigby medal of the Royal Geological Society of England.

F. W. MADERA has been appointed Pacific coast passenger agent of the C., B. & Q. Road, with headquarters in this city He succeeds T. D. McKay, who resigned last Decemher.

THE GOVERNOR has appointed E. E. Leake, of Woodland Commissioner of Public Works, vice A. H. Rose, term expired. The position is for four years at an annual salary of $4000.

COL. JNO. WEIR, of New York, who was here recently, and bought considerable mining machinery, has had it sent to Sonora, Mexico, where he has secured title to the La Mexicana, in the Ures district.

J. T. GRIBBLE is the new superintendent of the Reward mine, Nevada City, vice Jos. Thomas, resigned. Mr. Gribble was for many years foreman of the Yuba mine and of late has been superintending a mine in Tuolumne Co.

IRVING M. SCOTT has returned from Washington, D. C. He is favorable to the idea that one torpedo boat and one battle ship will he huilt here. The former will cost about $240,000; the latter over $4,000,000. It will be some weeks yet before the committee report will he made public.

W. L. AUSTIN is investigating the Empire mine, near Georgetown, Col., with a view of erecting a 250-ton smelting plant. The Empire ores have been subjected to the Fuller process at the Equator mill. By this process the ore is pulverized to a fineness of about 300 mesh and forced through quicksilver.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

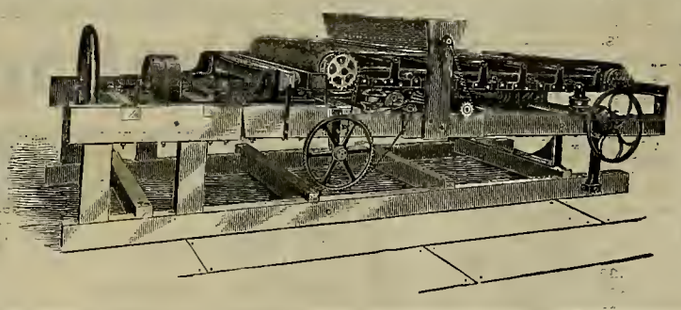
NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1895.

THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one third the cost in wear of any other crusher on the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

The Pelton Water Wheel Company, General Western Agents.

121 Main Street, San Francisco, Cal.

Scientific Progress.

Testing Precious Stones.

At a recent meeting at the Imperial Institute H. A. Miers, of the Mineral Department of the British Museum, read a paper on "Precious Stones and How to Distinguish Them." Mr. Miers confined himself rigidly to a few scientific matters, without laying claim to any artistic or expert knowledge, and simply endeavored to make it clear that gems can be easily distinguished by any one who knows the way. He said that he had always been forcibly impressed by the fact that the experts did not seem in the least aware of the simple and certain methods which had been placed at their disposal by recent mineralogical research. There was, perhaps, no subject on which experts had been so slow to take advantage of practical methods supplied by science as the manipulation and discrimination of precious stones.

Mr. Miers described these methods at some length, says *Invention*, illustrating them by means of lanteru slides, urging that they should be generally employed by gem experts. The polarizing microscope and spectroscope, he said, were easily used, and the former could be always used effectively by immersiug the stone in oil. Among uew practical methods introduced by recent discoveries were the use of the reflectometer and the recognition of tourmaline from its electrical properties by means of powdered red lead and sulphur. In place of the chemical balance for the determination of the specific gravities heavy liquids were recommended, and attention was specially called to a wonderful new liquid—fused uitrate of thallium and silver—in which all known gem stones float. Gem stones were far more numerous than was commonly supposed, although they ofteu passed muster under erroneous names. That the available varieties were uot more numerons was due mainly to the prejudice of the purchasers, who had heard of nothing but diamonds, rubies, sapphires and emeralds.

Decomposition of Water by Iron.

Iron is said to be incapable of decomposiug water at ordinary temperatures, except in the presence of air or by galvanic action, when some electronegative substance is connected with it. For this reason we should expect little corrosion from rust in the interior of a boiler, as air is only periodically admitted when the boiler is cooled down. There is, however, the dissolved air of the feed, and this is reduced in amount when the feed water is previously heated. Under any circumstance the rust found iu the interior of a boiler is of a different character from ordinary iron rust. It is, in the first place, of a much darker color. That formed in the upper spaces by steam alone is almost black, partaking of the nature of that black magnetic oxide which is formed in the Barff process by steam heated to 940° F. The latter oxide is, of course, completely protective when ouce formed, and the oxides formed in the interior of a boiler, although not of a protective nature, are, nevertheless, far less corrosive in their actiou than those formed under ordinary circumstances. This is another reason for supplying a pure feed water to steam boilers. The corrosion of the interior, when not assisted by adhesive deposits and organic acids from the lubricants, is comparatively slow, and the life of a boiler may be greatly prolonged by the exercise of care in this particular.

Edison's Latest.

The North Americau Phouograph Company, which went into the receiver's hands last Augnst, has had absolute control of the phonograph. The compauy could not pay its indebtedness to the Edison Phonograph Company and to Thomas A. Edison, and thus was forced to go out of business. Edison, as an individual, offered $125,100 for its entire assets, and the offer has been accepted. In speaking about the matter, he says: "The company has one asset which I am willing to pay a high price for—that is, a claim on all my future inventions and improvements of the phonograph. I do not care to have any one else have a lien on my brains, so I made a bid which proved higher than all others. I shall manufacture the phonographs myself now, and expect to keep all promises I made when I first introduced them. I am going in for the households, instead of nickel-in-the-slot machines, and in a short time I expect to produce an entire opera or a complete novel on a cylinder. It will cost a good deal, but it will pay me.

"I suppose it will cost me $2000 to have the opera of 'Norma' sung to the machine, bnt I can reproduce that on almost as many cylinders as I please. I think I can afford to pay more than the reporters, so that any gentleman can have 'Trilby' read to him in his parlor iu the course of an evening. I shall manufacture the perfected phonograph individnally."

Wheu asked, "What is the latest?" Edison replied: "Nothing at all, except the kinetophone, the combination of kinetoscope and phonograph. I am going to reproduce the motions and words of life-size speaking figures. I have already got a speaking and moving figure up to half life-size. Lately I have paid more attention to my mine than to anythiug else, bnt very soon I will get to work in my laboratory again."

Sir William Thomson has recently calculated that the average size of a chemical atom is not less than six and not greater than sixty billionths of a cubic inch. It has also been calculated that in a cubic inch of air there are three hundred quintillions of atoms. Heuce the cubic inch of air is by no means full, and it is possible for them to move eighteen miles a minute and collide against each other 8,500,000 times a second, as has also been lately calculated that they do.

Selby Smelting and Lead Company,
416 Montgomery Street, San Francisco.
Gold and Silver Refinery
—AND—
Assay Office.
HIGHEST PRICES PAID FOR GOLD, SILVER AND LEAD ORES AND SULPHURETS.
Manufacturers of
BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.
Also Manufacturers of
STANDARD SHOT-GUN CARTRIDGES,
Under Chamberlin Patent.

John Taylor & Co.
Importers and Dealers in
Assayers' Materials,
Mine and Mill Supplies.
Also Chemicals, and Physical, School and Chemical Apparatus.
63 & 65 First St., Cor. Mission, San Francisco.
We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.
Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

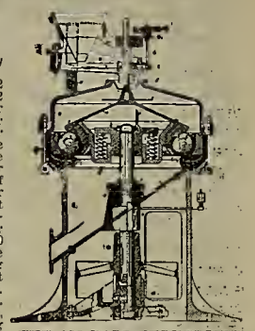
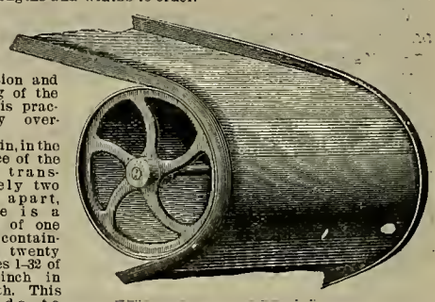
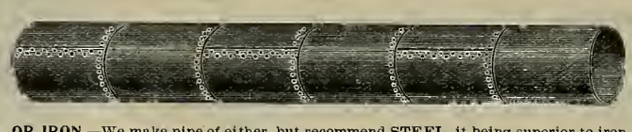
THE AMERICAN MINING & MILLING MACHINERY CO.,
121 Euclid Ave., CLEVELAND, O. 280 Caxton Blk., CHICAGO, ILL.
SPECIALTIES:
AM. CRUSHER AND AM. BALL PULVERIZER.
The simplest, cheapest and best machines in the market. Pulverize wet or dry to any degree of fineness. Make little or no slimes in wet nor dust in dry work. Four sizes, capacity from 2 to 60 tons per day.
SEND FOR CATALOGUE.
Cable Address, American.
First Prize and Gold Medal Awarded by World's Fair, 1893.
Office of The Cleveland Iron Ore Paint Co. and The Garry Iron Roofing Co., Cleveland, O., Jan. 25, 1894.
The American Mining & Milling Machinery Co., Cleveland, O.:
Gentlemen:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4⅞ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows less; in fact the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with less than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quality, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,
Cleveland Iron Ore Paint Co.


THE AM. BALL PULVERIZER. Morris Patent.

Blasdel Improved Concentrating Belt.
We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines; and make all lengths and widths to order.
Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.
Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.


H. G. BLASDEL, JR., Manager,
419 California Street, Haywards Building.....San Francisco.

Attention Miners!
W. W. MONTAGUE & CO.
—ARE MANUFACTURERS OF—
Riveted Iron and Steel
Water Pipe
For Hydraulic Mining, Mills and Power Plants.
IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.
309 to 317 Market Street, San Francisco.

Mining Pipe!


STEEL OR IRON.—We make pipe of either, but recommend STEEL, it being superior to iron in many particulars and inferior in none.
COATING.—We use great care in COATING our pipe with a HOT solution of Double Refined Asphaltum and Maltha.
COMPETITORS.—Our competitors say we have the best appointed Pipe Shop on the Coast.
SCHAW, INGRAM, BATCHER & CO., Hardware Merchants,
SACRAMENTO, CAL.

FRANCIS SMITH & CO.,
—MANUFACTURERS OF—
SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.
Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.
130 BEALE STREET, SAN FRANCISCO, CAL.
Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Mechanical Progress.

The Future Newspaper.

Progress in the production of newspapers during the last half century leads one to consider whether, with the fast perfecting press and the type-setting machines, perfection has been reached. The writer thinks not, but firmly believes that both press and type of the present patterns will in a very few years be things of the past.

These results will be brought about by a combination of lithography and telegraphy. The fast press printing from stereotype plates on cylinders will be superseded by an adoption of the lithographic press, also probably using cylinders; but as it would be impossible to use lithographic stone in this form, a zinc plate prepared with a coating of pyrogallic acid and gum, to enable it to hold water, will be substituted.

This is by no means a new idea, as it is well known to engravers, and it would dispose of the perfecting press in its present form; but by mounting the zinc plates type-high, with a little modification, a similar press would do the work.

The principal change would occur in the composing-room, which would feel the effects very greatly. It will not be necessary to use a line of type in the news columns. The news will be furnished in column width from the associated or other news center, printed on transfer paper, with transfer ink, by a machine something after the fashion of the present type-writing machine.

This matter will be duplicated by electricity to all subscribers simultaneously, and by them transferred to the prepared zinc plates. Electrical devices are already in use by which signatures, drawings, etc., can be made at one end of the line and duplicated at the other. It then requires only a slight stretch of imagination by those who keep track of scientific progress to realize the possibility of sending an imprint of type by the same process.

An Average Day's Work.

A day's work even for the average workman of full power, says Professor Thurston in the *Industrial World*, varies greatly with the nature of the work and the method and facilities of its performance, and the same is true of the horse and other animals, but in less degree usually.

The most powerful horses may be expected to develop, as an average, two-thirds of a horse power for eight hours a day, twelve million foot-pounds per day, very nearly, under favorable circumstances. The work of a man is variously given by different writers, but it is usually stated to be not far, at best, from two million foot-pounds a day in the treadmill, ascending mountains and stairways, when his own weight is the useful load, and carrying burdens on a level. Weisbach gives as maximum figures 1,935,360; Rankine gives 2,088,000, while Ruhlmau states the work of a Prussian soldier, carrying a knapsack and other accoutrements weighing a total of sixty-four pounds, as about 3,000,000 foot-pounds.

We may safely take two million foot-pounds per day as a figure to be compared with the ten million foot pounds of energy supplied, and as giving a fair maximum for the efficiency of the animal considered as a prime motor. It is 0.125 horse power for eight hours; 0.04 for the day.

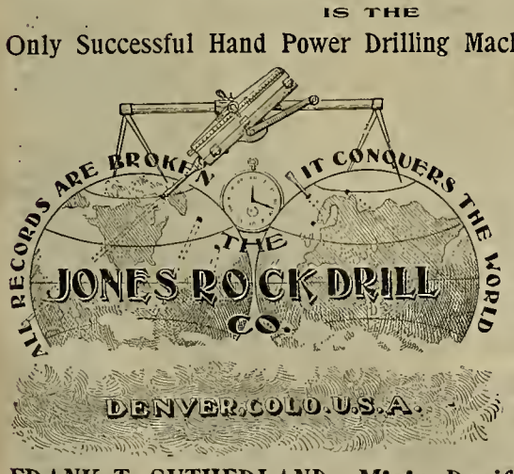
The various plans for the Berlin Exposition of 1896 are being advanced with considerable energy. The exhibition will be instructive and representative, and due consideration is being extended to the attractive side of the programme. It is proposed to build a Cairo street; the idea is neither new nor original but is likely to succeed, as special attention is being devoted to its realization. The Cairo street is intended to cover an area of 25,000 square meters, and the building materials will be of a more solid nature than are generally used for such purposes. It is also proposed to have an Egyptiau panorama and diorama. A panorama, which will be of very large dimensions, will represent the famous Ziller valley in the Tyrol. It is also under discussion to have an aquarium, a huge glass reservoir containing as many of the animals and plants of the sea as possible. The aquarium will be so arranged that it can also be inspected from the bottom. Further, there will be a captive balloon, which will possess several new features, the German military balloon department being celebrated for its ability and all its inventious and improvements will be embodied in the balloon in question. The balloon will for every ascent be fitted with a registratiou apparatus, which will register height, temperature, moisture of air, etc., also an apparatus for registering the temperature of the gas in the balloon, and experiments will be made in transferring the gas, no longer needed in the large balloon, to smaller ones. The captive balloon will be in telephonic communication with the earth and it will also carry a photographic apparatus. In conuectiou with the balloon demonstrations will be a large and varied collection of all possible exhibits connected with balloons, their handling and filling, etc.

The tensile strength of iron at 400° below zero is just twice what it is at 60° above. It will take a strain of sixty instead of thirty tons to the square inch, and equally curious results have come out as to the elongation of metals under these conditions.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

CHARLESTON DISTRICT.

At Forty-nine Flat Boles & Hadley are running their gravel claim. The Acme mine will he started up next week.

PLYMOUTH DISTRICT.

The Alpine mine is reported sold "to rich capitalists." A two-cent assessment has been levied on the Bay State. The Pioneer mill and mine are running steadily.

JACKSON DISTRICT.

The New York Electric Company have sued Sheriff Gregory for $8000, damages alleged to have been sustained hy plaintiff in the attachment of certain electric machinery at the Gover mine. He attached the machinery with the other property, but has sold none of it.

The Kennedy Miuing Company have bought R. Atkin's interest in the Clyde quartz mine, adjoining the Kennedy ground, for $1500.

PLYMOUTH DISTRICT.

BAY STATE.—The Bay State is running north ou the 600 level and stoping out from that toward the 500. The mill runs steadily and is in free gold, pounding out a little more than expenses. They have not had any of their sulphurets treated yet.

THE GWIN—MIDDLE BAR.—The sinking continues steadily and rapidly. It is but eleven months since the workmen went on to the ground to survey and to-day the property has an excellent double-drum water power hoist which has worked without stopping almost since it was installed. The shaft of two compartments and a ladder-way is now down 650 feet. At present they are singularly fortunate with relation to the water, for they are lifting less than 3000 gallons, more than two-thirds of which is tanked at the 300 level.

Butte.

OREGON CITY.—On the Mascot a shaft is heing sunk from the lowest tunnel. Steam power will soon he in use: the shaft will he sunk 300 feet. There is more timber there now than twenty-five years ago. Then the big trees were cut down for wood required by the quartz mills, and have been replaced a second dense growth.

Calaveras.

ESMERALDA.—Preparations are heing made to work the Gum Boots mine, which has been bonded to Salt Lake capitalists. This mine is situated on Indian creek, and has been worked several years hy its present owners, Bosovich & Co., who have erected an arrastra for crushing the ore.

Madera.

FINE GOLD DISTRICT.

The ditch from the North Fork for power for the Mountain View mine is finished. The twenty-stamp mill will he huilt in the next ninety days.

Nevada.

LIVELY WORK SOON.— *Transcript:* Work of a permanent nature will soon he inaugurated at the Red Dog gravel mine, near You Bet. A tunnel will he driven to tap the channel, where good results are expected. At present the company are rewashing the old canyon tailings.

BONDED THEIR MINE.—*Transcript:* W. J. Britland and John Graves have bonded their quartz mine to San Francisco parties for $5000. The mine is situated on the hill above Delos Calkins' place, at Selhy Flat. L. P. Goldstone of Grass Valley and Mr. Bandman of San Francisco are representing the company that has the hond, and they intend to begin work soon. Samuel Blight of Grass Valley will have charge of the mine. One-fifth of the proceeds of the property will go to Britland and Graves until the purchase price is paid or the hond expires.

GETTING READY TO HYDRAULIC.—Preparations are heing made to work the Polar Star mine, near Dutch Flat, hy the hydraulic process. W. F. Englehright was over there last week surveying for an impounding dam and other work that must be done before a permit to hydraulic can issue from the Debris Commission. John Spaulding is the principal owner of the Polar Star, which in years past paid handsome dividends to the owners. With the closing of the hydraulic mines it was rendered a non-producer.

ENGLISH MOUNTAIN.—*Herald:* There is seven feet of snow at English Mountain now and it is reported that Supt. Keniston has resigned and that a competent man has heen appointed in his place.

Placer.

GENERAL MINING NOTES.—*Sentinel:* Rathburn, Johnson and Iverson are running a drift at their mine 1½ miles southwest of Blue Canyon.

W. F. Jackson, of Crocker's Art Gallery, has a claim near Blue Canyou. He has his survey made and will start a tunnel the first of this month.

H. K. Develey has a force of men driving a tunnel at his gravel claim, one mile west of Blue Canyon. Prospects look flattering and he will soon put on more men to push his tunnel to completion.

The four-stamp quartz mill of John Sipp & Co., near Blue Canyon, has been crushing ore all winter. They are working what is familiarly known as the old Red Stone quartz ledge, and they will put on more men this spring.

George and John Clark of Nevada City have honded the "Montreal" mine at Meadow Lake to parties in Salt Lake. The majority of the money has heen paid down and the balance will he paid Aug. 31. The camp of Meadow Lake will take on a new life this summer.

J. E. Shettle, who purchased the Wash ington mine in Old Man mountain last year, s ha let a contract to run a tunnel and crosscut the ledge.

AROUND OPHIR.—*Herald:* B. M. Berry has sold a three-fourths interest in the Kittler mine at Ophir to foreign parties. A contract has heen let for 200 feet of tunnel in addition to the present 100 feet. A pay chute has been struck with a streak running through it which has heen assayed hy Selhy at $451.75 a ton. The entire ledge will prohably go $60 or $70.

W. F. Whitney of Seattle has hought interests in the Coleman, Workman and Grass Ravine mining properties helow Ophir. He is also interested in the opening up of the Adams claim.

Plumas.

MINING BEGUN.—*Bulletin:* On Monday the Quincy Mining and Water Company got the water through their ditches and down to the mine. The next day one hig monitor was set to work at Gopher Hill, and in a few days others will be started. The company is prepared to operate five this year, whereas only two were in use last year. A rock dam higher than any in use last year has been constructed across Wauponse Creek largely increasing the capacity of the settling reservoir used hy the company for the storage of tailings.

This mine is now fully equipped for a long season's work. The water supply will be the hest had for years. At the hase of Spanish Peak, the source of the water supply utilized later in the season, the snow is now 14 feet deep and solid, holding immense quantities of water, which will he freed gradually as the season advances.

No compauy in this part of the State has equal facilities for cheap and effective mining by the hydraulic process, and it controls over 2000 acres of valuable mining ground located in a region which has always yielded large quantities of gold.

San Bernardino.

AT VANDERBILT.—In the Gold Bronze mine there is more ore in sight than at any previous time in the 250-foot level, there being a block of ore 200 feet long aud 100 feet high. There is also considerable ore in sight in the 150-foot level. There are twenty-three men on the payroll. A carload of concentrates averaging $60 to the ton was shipped last week.

Robert Patterson of White Hills has bought a two-thirds interest in the Phelps mine at Crescent, and taken men to work there.

San Diego.

AT PINE VALLEY.—Twenty men are employed, working night and day shifts, in J. G. Cortelyou's mines. A two-horse team takes the ore down the new mile and a half grade, keeping the five-stamp mill busy pounding out gold. Hauck brothers are developing a rich ledge, sinking a shaft which is now down over thirty feet. They will ship ten tons of ore this week to the National City reduction works.

THE RICE GOLD CAMP.—Several new strikes are reported in Rice gold camp, east of Warner's ranch. The prospects now heing developed are looking so well that mining men are showing an interest in the district. Mr. Moulton of Perris, believed to represent the owners of Good Hope mine, has acquired control of the Hillside and Pine Ridge mines at Rice, and, in company with Foreman McGeary of Warner's ranch, is developing the properties by sinking a shaft, running a tunnel and making arrangements for a mill. The Bertha and Daisy, owned hy Harrison and Rice brothers, are showing extra good rock.

Shasta.

FRENCH GULCH.—*Free Press:* Ellery brothers, who cleaned up over $1500 from twenty tons of ore last week, are still doing business on the same lines, and will clean up $2000 this week. Their sulphurets also assay up in the hundreds.

The Gladstone is working the usual force of men and will probably show a net profit of $8000 for the past month, as against $5500 for the preceding month.

The Washington still runs steadily, and the hullion shipments are heavy. Late developments in the mine are a surprise to the owners.

The Niagara shows good results.

Considerahle prospect work is heing done on several mines near the Tower house.

TRINITY CENTER.—Several large placer deals are reported in a fair way to consummation.

A French Gulch syndicate are the reported purchasers of Jack Strode mine. This mine shows a fine lot of ore chutes milling from $50 to $100 per ton. The five-stamp mill will he increased to ten.

CINNABAR.—The Altoona is working along quietly. It is understood that their product from one furnace aggregates ten flasks daily. The snow is from fifteen to twenty feet deep.

THE BASE RANGE.—The property of Butler & Sons, under bond, is heing developed by a San Francisco syndicate.

Near Kennet a new discovery of low grade gold ore is reported.

At Squaw creek a new combine is reported to be examining the Riley mine with a view of purchase. They think that by spending from $25,000 to $30,000 the property can be made productive.

The Uncle Sam mill and mine dump over a hundred tons of tailings into Squaw creek daily and send out a corresponding amount of hullion. No stops or hitches occur in this management. The large ore reserves and dead work insures an ore supply for a year to come.

The owners of the Balla Klalla at Windy camp are trying to float their properties in Philadelphia. A small force of men are at work under Colonel Ellis and Weil.

IRON MOUNTAIN.—The surveyors are still setting stakes for the new railroad. It looks as though the hills would be denuded of timher making stakes for various surveys. The right of way has been secured across several pieces of property, hut there is no telling when the surveyors will get through. Copley seems to be the terminus decided upon. The Iron Mountain mill has been thoroughly overhauled and is ready to run as soon as wood can be obtained. This week there were eighty-one men at work in various capacities about the mill and mine.

The Power company started their men clenring brush and setting stakes last week in the canyon above the Calumet on Spring creek. Four hundred electric horse power will be dcvelcped and turned into electric energy to be rented out to the various mines in the vicinity.

MISCELLANEOUS.—The Kosciusco has ten stamps pounding away and the miners are at work in the tunnels.

Redding parties have secured a bond on the Afterthought and Donkey mines at Furnaceville, and will undoubtedly create a boom in that district.

The Tellurium mine on Salt creek is getting in their new machinery, putting in tramways, etc.

Charles Jones and Hans Christisen's new mill at Muletown is to be supplied with a large eugine and boiler. It is now grinding from four to five tons daily.

Bullychoup is still covered with snow at least twenty feet deep.

NEVADA.

Storey.

SAVAGE AND CHOLLAR.—In the Savage, on the 950-foot level, the south drift started from the face of the sill floor, southeast drift, was advanced 22 feet; total distance, 80 feet, at which point it connected with an upraise from the 13th floor of the south ore stopes. This connection gives good ventilation and enables them to prospect this section of the mine advantageously.

During the week most of the men have been employed in repairing and retimbering the main hoisting shaft between the 850 and 950-foot levels.

The bullion statement of the Chollar for March is as follows: Worked at Nevada mill 820 tons of ore; gross proceeds in bullion, $19.661; cost of reducing, $4,920; net proceeds in bullion, $12,277; assay value per ton, $27.76; gross average per ton, $23.98; net average, $17.98. Mill worked 88.2 per cent.

OFFICIAL REPORTS.

CROWN POINT.—The east crosscut from the south lateral drift on the 700-foot level, 105 feet south from the shaft, is now out 52 feet. It has been stoped, and they are now preparing to raise from it in the quartz, the latter ruuning from $5 to $8 per ton hy face samples. It is the intention also to run north from fourth floor of the stope to connect with this raise, which work will be started within a day or two.

Have extracted during the past week from the openings on the 600-foot level and between it and the 700-foot level 514 tons of ore, which has been shipped to the Mexican mill for reduction. The hattery sample for the week has averaged $10.41, of which $9.31 was gold.

Have shipped to the Carson Mint one har of hullion valucd at $17,135, the cleanup for March.

BELCHER.—On the 300-foot level the joint Belcher and Seg. Belcher south drift is now 31 feet from the Belcher shaft, and the face shows porphyry.

Hoisted during the week and stored in the ore hin at the mine 38 tons of ore, the average top car samples of which show an assay value of $35.12 per ton.

SEG. BELCHER.—On the 200-foot level the main south drift is in 464 feet from the Belcher shaft, having been advanced 10 feet. The face shows porphyry.

Have hoisted during the week and stored in the orehouse at the mine 12 tons of ore, the average top car sample of which shows an assay value of $49.64 per ton.

ARIZONA.

HARQUA HALA DISTRICT.

CARGO MUCHACHO.—*Times:* The Paymaster mill will soon commence running again on ore from the Padre, located a mile and a half from the mill. An eighty-foot shaft has developed a good hody of ore.

SALE OF THE OLD DESERT.—John Llewellyn and C. J. Kimhall disposed of a hond on the Old Desert mine to James Wakeman of Connecticut, retaining a one-third interest in the property. They bonded the mine three months ago. The Old Desert lies eight miles north of the Bonanza. It was located about twelve years ago and a great deal of work has heen done on it since. There is said to he now not less than 200,000 tons of ore in sight. The ore is partly free milling, partly concentrating and very rich. A mill will be erected at once. Enough power will be arranged to run a 60 or 100 stamp mill, though so many stamps will not he employed in the beginning.

THOMAS CAMP.—The shaft on La Fortuna is now down twenty-five feet and the six-by-eight opening is all in ore, with the hanging wall not yet in sight. Twelve tons of ore are sacked ready for shipment, which, it is estimated, will go from $100 to $200 per ton. There are on the damp seventy-five tons. About twelve ounces of free gold have been concentrated from the refuse. The New Year's Gift is being opened up hy Wm. Halbert and shows free gold in horn from croppings.

The country is granite, porphyry, schist, shale and quartzite. The footwall is quartzite, schist and shale in gangue. Porphyry shoots up through formations and granite predominates as the contact. Veins run with the country. White spar and white quartz cap and shoot through almost all formations, also run through the hills regardless of lay of country. In the Providence and La Fortuna gold has been found in the schist.

REPORTED BONDED.—*Journal-Miner:* It is reported that the famous Bullard mine in the Harcuvar mountains has been bonded for $500,000. It is to he hoped the report is true, for this is one of the largest and hest mines in Arizona, and will doubtless be worked on a very large scale, giving employment to a great number of men and putting a large amount of money into circulation. This mine is only about twenty-five miles from Congress station, S. F. P. & P.

CASTLE CREEK DISTRICT.- Supt. Lindsly of the Whipsaw Mining Company has the ten-stamp mill owned hy the company ruuning day and night. The ten-stamp mill of the Swallow Mining and Milling Company is in full operation, and K. Barrett has his mill on the Trade Mark running a considerable portion of the time.

THE MARICOPA COPPER CO.—Phœnix *Herald:* Out of the debris of the wreck of the Harcuvar Copper Company, owning extensive mining properties in this and Yuma counties, there has sprung a new company known as the Maricopa Copper Company, organized under the laws of Illinois. The new company is composed of members of the old company, who have sufficient faith in the properties controlled to develop and work them. Frank Prange, of the new company, is now in Phœnix making arrangements to start up the copper properties, and soon men will be at work and stamps dropping on the ore.

BRITISH COLUMBIA.

OWN TWO MINES.—The Great Western Mining Company was incorporated on the 1st inst. under the laws of the State of Washington, with a capital stock of $1,000,000. The directors of the company for the first six months are John M. Burke of Cœur d'Alene county, Idaho, Chas. S Warren of Butte, Chase Barr of Rochester, Ill., and D. M. Drumgeller, Jarvis R. Jones, H. M. Stephens and Louis E. Bertonneau of Spokane.

The company is the owner of the Great Western and Gold Chariot gold mines at Trail Creek, B. C. The ore of the Great Western property is like the Wnr Eagle and is about four feet in width. The shaft on this property has only reached a depth of twenty feet, all in ore, and it is expected when the contract now let reaches the 100-foot, levels will he extended each way on the lead. Work will be started on the Golden Chariot as soon as the Great Western contract is finished.

COLORADO.

RAPID DROP STAMPS.—*Ores and Metals:* The new rapid-drop stamp mill of the Iron City Mill Company in Black Hawk is about completed, and will be started up this week or the week following on custom ore. It will have a capacity of twenty-five stamps, equivalent to fifty stamps of the slow-drop style.

IDAHO.

WALLACE DISTRICT.

THE MAMMOTH MINE.—The Mammoth mine, which C. L. Hathaway is operating in Pony gulch, near Delta, is employing a dozen men. Mr. Hathaway is satisfied with his experiments with the Crawford mill, which he put in thero, and has just shipped another over to the mine. The ore runs from $112 to $170 per ton in gold. The property consists of a blanket deposit, which is explored hy half a dozen tunnels ranging in length from 150 to 190 feet. The Crawford mill is supposed to treat ten tons per day with a 200-mesh screen, hut at the Mammoth thirteen tons per day are put through a 100-mesh screen, which is as fine as they require it.

RUN HIM OUT.—Last Saturday J. Mills was run out of the Gem mine hy six masked men, all armed with revolvers. He was drilling a hole in a raise with one companion, and the leader of the gang had him covered with his gun before he saw them. Three of the men arranged themselves ahead of him and three behind, and in that way he was taken out of the mine. No arrests have been made. Mills is one of the pioneers in the Cœur d'Alenes.

MONTANA.

A seventy per cent interest in the Minnie, the Minnie Extension and the Great West gold properties, located in the Natural Bridge district, twenty-five miles south of Livingston, has been bought hy Paul Zuber for $7,500. This property is now owned by Zuler and Thompson Bros., of Livingston, who expect to begin mining operations on all three mines early in the spring. A stamp mill is to he erected and development work pushed during the summer.

THE GILT EDGE.—*Inter-Mountain:* The Gilt Edge, in Ferguson county, is shipping gold hullion twice a week, averaging about $3500 per week. The ore averages $30 a ton, and the company is putting through about forty tons a day. The tailings are run down to from ten to sixty ccnts a ton.

OREGON.

BLACK SANDS.—The St. Paul men who are working the hlack sand deposits on the heach north of Bandon are putting in two new machines for extracting the gold, and are highly elated over their success in handling the sand.

IN GRANT CO.—Thomas Jones, John Stam and Aaron White are opening a new quartz mine on the headwaters of Wolf creek, about twenty miles southeast of Prineville. They have run an open cut on the ledge a distance of 120 feet, and are now twenty feet below the surface.

UTAH.

BEAVER LAKE DISTRICT.—H. Joseph has signed the hond of the Banty claim in Beaver Lake district to Captain J. R. De Lamar. The bond is for $20,000, and is for six months. De Lamar has contracted with Joseph and Douglas for fifty feet of shaft.

TWO MINING DEALS.—Capt. J. R. DeLamar has hought a half interest in the Golden Gate group and other properties adjoining the Mercur. The property covers fifty acres of surfaoe. The ores run from $9 to $15 per ton in gold. The ores are very refractory and volatile. Reduction by roasting showed a loss of 22 per cent, while chlorinization gave a

loss of 34 per cent. A check on Wells, Fargo & Co. for $35,000 is reported to have been passed over as the first payment.

In addition to the half interest in the Golden Gate group, Capt. De Lamar also purchased a half interest in the lease and bond now held by Messrs. Butts and Neill on the Viking group, adjacent to the Goldon Gate, and covering fifty acres.

The properties thus acquired by Capt. De Lamar in the Mercur district give him an interest in the gold belt covering more than one hundred acres, and is a larger property than the Mercur itself. For the present nothing but development work will be done. George Kislinghury, formerly State Mine Inspector for Colorado, and an old miner and journalist, will take charge of the works.

Capt. De Lamar will spend the summer cruising on his yacht.

DE LAMAR'S PROCESS.—The De Lamar *Lode* gives the following description of Capt. De Lamar's new cyanide mill, in which he has adopted a process of his own, and which may be used in the Golden Gate:

"The ore, which is deposited by a tramway into a fifty-ton bin, goes to the platform, where the labor of one man is required to put it through the rock-breaker, and it is then conveyed on to the dryer. From this it is taken by an elevator to two hoppers, from where it is fed into the rolls and then conveyed by another elevator to the screens. In the rotation of the screens the coarse material drops back into the rolls, while the fine material passes on through a patent self-sampler and on to a self-weigher, a personal invention of Mr. Cohen's. It is then conveyed to the roaster; and, after being treated here, it goes through the cooling process and into bins, from where it is emptied in five tanks and treated with chlorine gas, where it stays for a certain length of time, and is then emptied into the precipitating tanks below. All of the work is performed by machinery, and it was demonstrated by the first run that, without forcing the work in any division, ten tons more material could be put through than was expected. The capacity of the mill is fifty tons, and the first report gave ninety-eight as the working percentage. The entire plant covers about three acres, and every enclosure has a corrugated iron roof, while the lining of the precipitating tanks alone contain twelve tons of lead. In connection with the works is one of the most complete assay offices to be found in connection with any mill, a fully equipped machine shop and electric-light plant, with one of the finest offices in the Western country. In the erection of the buildings every precaution was taken against fire, as, in addition to the large storage tanks which are connected by pipe, there is a large pump in the main building. There are also electric signals in all parts of the mill by which the machinery may be started or stopped in an instant and alarms given. The whole structure, which is an exhibit of mechanical skill, with a continuation of the present success, will be the salvation of Ferguson district."

GOLDEN GATE GROUP SOLD.—Captain De Lamar has closed a deal for a one-half interest in the Goldon Gate group of mines in the Camp Floyd district. The price, it is said, is $35,000, with the option to take the remaining half interest at $40,000.

REGRINDING VALVES

Reasons why LUNKENHEIMER'S are the best.
On the market for over 35 years. Made of Gun Metal throughout. Every valve tested and warranted. Can be reground while on pipe. Easily taken apart on account of outside thread and union style connection, therefore no "cementing" of hub to body. In long tried use on Government Vessels, Lake and River Boats, in Rolling Mills, Refineries, Factories, Mills, etc. Gun Metal is the only composition that will stand the screw power of valve stem and make a steam joint. Superior and more durable than valves with Asbestos or Rubber Discs. Try them and be convinced. None genuine unless "LUNKENHEIMER" is cast in the shell. Specify and insist upon "LUNKENHEIMER'S." Catalogue gratis upon request.

Electrical Progress.

Making Climate as Desired.

Prof. F. B. Crocker, of Columbia College, is an electrical scientist whose utterances are entitled to some attention. Regarding the probability or possibility of controlling the weather by means of electricity, to "make rain," or cause fine weather, the Prof. says:

"It is difficult for the most conservative man to set any bounds to the possibilities of what electricity will one day accomplish. Of course, there is one great fallacy in the popular mind, and that is that we know very little about electricity. On the contrary, we know a great deal. Electricity is to-day one of the most exact of all the sciences. On the other hand, it is perfectly fair to say that we have hardly begun to put this agency to the various uses which will be made of it in the future. In a word, while we know a great deal about it, we have only just begun to perfect mechanical devices for applying and utilizing it.

"I do not know that it would be at all impossible to make rain by electricity. The discoveries of Lord Rayleigh and Prof. Oliver Lodge are very well known to science, and have led to many interesting experiments. For example, a current of electricity applied to a broken or interrupted jet of water will make the stream perfectly smooth and continuous. One great difficulty in making rain by this means would be that of securing an effective discharge of the fluid. However, it might be feasible to send up a balloon from which could be suspended a large circular ring, with a large number of sharp points sticking outward, and connected by a fine wire with a high-tension dynamo or influence machine below. Whether this would secure the desired end, I am not sure, as air, you know, is a very bad conductor. It is a thing that would have to be exhaustively tested by actual experience. Perhaps the greatest difficulty to overcome would be that of effecting the discharges of electricity in the proper places and at the desired altitudes.

"I think it is entirely probable that within another decade we shall have solved practically the question of aerial navigation. Not that this problem is so very easy; but it presents no more difficulties than hundreds of other similar mechanical problems have, and there is no more reason to suppose that we shall not build a successful air ship than there was reason to suppose a hundred years ago that steam could not be applied to the propulsion of a train of cars along a smooth track or of a ship across the ocean. And, of course, if we get an air ship that can be easily operated, and will carry a considerable weight, then it will be very easy to load a ship with storage batteries containing a big electrical supply, sail up into the clouds, and discharge the electricity wherever we want it. In a word, if it is found that we can make rain by an electrical discharge, and we want to do it, it will not be very long before we shall find ways and means of doing it.

"Of course, it would still remain to be seen whether there is actually enough moisture in the arid areas of the great West to precipitate a considerable rainfall.

"I do not know that I clearly understand the suggestion as to utilizing the heat of the tropics to modify the temperature of colder climes. The suggestion may be simply to utilize the heat of the sun's rays by means of a solar engine for the creation of electricity. This could be transmitted long distances. You know in the tropics, where the sun's rays are intense, the solar energy develops a force of about one horse power to each square yard of the surface exposed. Inasmuch as the sun's action is very nearly continuous in the day time, and but a little interrupted by clouds, this force is fairly reliable.

"But it seems to me there may be a much simpler device than this for modifying the climate. The simplest device would be to pump hot air from the tropical zone and cold air from the region of the Arctic circle. It would not be difficult, nor would it be very expensive, to construct a steel tube system of sufficient diameter to somewhat modify the climate of the Eastern seaboard.

"For example, a thin steel tube, say four or five feet in diameter, would convey an enormous quantity of air. One has really no idea of what this quantity would be until one stops to figure it out.

"The idea is identical with the pipe-line systems now in use. Oil is piped long distances from the oil wells of Pennsylvania, and, similarly, natural gas is piped long distances. Now, it would be just as easy and just as feasible to pipe air as oil or gas.

"The distance, too, is not so very great. I have been surprised to find how short a line would serve for this purpose. If it extended from within the tropical zone to within the Arctic zone, it would more than meet the requirements and still extend over only an eighth of a circle. It would be only about three thousand miles long. I do not think that it would require a pipe of more than four or five feet in diameter, and the pipe could be built of thin steel and need not be expensive. Such a line would not be nearly so costly to build and equip as a railroad line, nor does it present any material difficulties. It would be the simplest of mechanical problems, and the 'right of way' would not be expensive.

"For motive power some out-of-the-way waterfall could be utilized, so that the expense of operation need not be very great.

"I know all such suggestions as these are generally looked upon as coming from a wild-eyed lunatic; but there is really nothing half so daring in this suggestion as was the idea of laying a cable under the Atlantic. The difficulties to be overcome were greater then than any difficulties with which this enterprise would meet. We go to a great deal of expense to secure pure water. I don't see why it would not be just as feasible to provide means for fresh air and at the same time modify the rigors of our climate. Of course, the original heat or cold might be lost in transmission, but the air would always produce heat where it is compressed and cold where it expanded."

There are thinkers and dreamers in every branch of science and progress. Edison, Tesla and Bell show what thinkers can do. The gentleman interviewed above seems to belong to the class of dreamers.

It is said that since the introduction of the electric light, public performers are able to preserve their voices in better condition, being fifty per cent more often in good voice. They are cooler, do not perspire, and do not get husky.

PLACER

Amalgamators,

Dredgers,

Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.

Highest possible Gold yield insured.

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.

Crushing, Pulverizing, Concentrating and other machinery also built.

Investigation solicited.

JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

Points on Patents to Mines.

The recent decisions of the United States Land Office say in effect: Abandonment in its common law sense is purely a question of intention. An abandonment takes place when the ground is left by the locator without any intention of returning or making further use of it, independent of any mining rule or regulation.

Failure to perform the amount of work on a mining claim required by the local mining laws or regulations established and in force in the district where the claim is located amounts to an abandonment of the claim, and consequently it may be occupied and appropriated by another.

Foreign companies cannot set up an adverse claim to an unpatented ground.

If a joint owner of a claim is excluded from the notice of location, he has such an adverse interest as to entitle him to file an adverse claim.

When one is seeking a patent, and gives the required notice, any other claimant of an unpatented location objecting on account of extent, of form, or because of prior location, must come forward with his objections and present them, or he will thereafter be precluded from objecting to the issuance of the patent.

In the absence of a law to the contrary adverse claims may be filed on Sunday, or out of office hours, if the officers are willing to receive them, though they are not required to receive adverse claims or transact other business, except during regular office hours.

While the right to a patent is equivalent to a patent issued, yet the purchase of lands containing minerals under laws governing the sale of agricultural lands does not vest any rights whatever in the purchaser, for mineral lands are reserved from sale, and if no right to patent exists, it follows that a patent cannot be legally issued.

No distinction is made by the mining laws in the matter of location, occupation and appropriation of mining claims between the rights and privileges of a citizen and those of a person who has declared his intention to become a citizen.

Tellurium.

Any miner or prospector who has a blow pipe, alcohol lamp and a few drops of cold sulphuric acid, can, in a few minutes, determine whether tellurium is present in ores. All that is necessary is to break off a small piece of the ore, place it in a small porcelain dish previously warmed so as to avoid breaking, apply the blow pipe until the ore is at an oxidizing heat, then one or two drops of sulphuric acid on porcelain dish; allow to mix with the ore. The reaction will immediately follow, if tellurium is present, by beautiful carmine and purple colors.

Characteristics of Tellurium:—Tellurium is rather a rare element and was first discovered in 1782 by Muller von Reichenstein. The compact form is a silver-white resplendent metal of markedly crystalline structure. The crystals are rhombohedra and the ingot consequently is very brittle. Specific gravity is 6.2. The metal fuses at about 500° Centigrade and is distilled at a very high temperature. Its vapor is golden yellow and has a very brilliant absorption spectrum. A bar of tellurium becomes feebly electrical when rubbed with a woolen cloth. The electrical conductivity, like that of selenium, is largely influenced by the temperature previous to heat, and it increases after exposure to light, though not to the same extent as selenium does. Tellurium burns when heated in the air with a blue flame, evolving white vapor of tellurium dioxide. It is insoluble in water and carbon disulphide, but dissolves in cold fuming sulphuric acid, imparting to the solution a beautiful carmine color which almost immediately gradiates into a purple, that is probably due to the formation of a compound analogous to sulphur sesquioxide, namely STO_3, the tellurium being precipitated on the addition of water. On heating the sulphuric solution, the tellurium is oxidized, sulphur dioxide being given off. In the same way, it rapidly undergoes oxidation in the presence of nitric acid.

A FEMALE CODFISH will lay forty-five million eggs during a single season. Piscatorial authorities say that were it not for the work of the natural enemies of fish they would fill all the available space in the seas, rivers and oceans.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, April 11, 1895.

The weekly see-saw in silver sends it back to just the figures of a week ago. But like the toad that climbed four feet every day and fell back two feet every night, it will get out of the hole.

The following special from London contains some interesting information concerning the hi-metallic sentiment of the Australian colonies: "The Australian colonies have instructed their Agents-General to urge upon the British Government first, to permit each colony to be represented directly in any international silver conference that may be called, or if that may not be considered advisable, that the colonies conjointly may be allowed direct representation."

This important fact, which is learned upon authority, has not yet appeared in the London press. Agent-General Playford of South Australia has sent a letter to this effect to the Marquis of Ripon, the Colonial Secretary, but has not yet received a reply.

Several of the colonies, notably South Australia, produces silver, but while their own mints are allowed to coin gold, all receive their silver coin from the Imperial Mint in England.

New York Metal Market.

NEW YORK, April 11.—PIG IRON—Scotch, 19@20c; American, 9.50@12.50c.

Mining Share Market.

SAN FRANCISCO, April 11, 1895.

The Comstocks opened weak, and every stock showed that despite the advance in silver, the encouraging official reports from the mines and the plentitude of money, the lack of leadership prevented anything like business on the street. There was an advance on Wednesday that a little nerve could have and would have sustained.

The following illustrates the changes of the week:

MINES.	4	11

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING APRIL 2, 1895.

536,982.—TREE PROTECTOR—C. W. Anderson, Los Angeles, Cal.

536,683.—FLOATING DOCK—J. J. Cousins, S. F.

536,610.—DOOR CASING—E. G. Durant, Pasadena, Cal.

536,721.—REFRIGERATOR CAR—J. M. Gilstrap, Sacramento, Cal.

536,927.—FIRE ESCAPE—J. L. Gregory, Washoe, Nev.

536,874.—EXHAUST NOZZLE—E. W. Harris, Palisade, Nev.

536,876.—STUMP PULLER—E. W. Jones, Portland, Ogn.

536,754.—SOCKET WRENCH—E. E. Masten, Sacramento, Cal.

536,756.—DREDGER—C. Meier, S. F.

536,757.—LAMP STOVE—W. R. Myers, S. F.

536,893.—AMALGAMATOR—N. L. Raber, Corvallis, Ogn.

536,704.—CAR SAFETY GUARD—G. Rischmuller, S. F.

536,842.—WATER MOTOR—R. C. Shepherd, Redlands, Cal.

536,767.—UMBRELLA AND FAN—M. Stocklmeier, Los Gatos, Cal.

536,822.—SAW HANDLE—John Tors, Fort Bragg, Cal.

536,769.—FLUSHING DRAIN PIPES OF SINKS, ETC.—F. B. Vinter, San Jose, Cal.

536,770.—FLUSHING DRAIN PIPES OF SINKS, ETC.—F. B. Vinter, San Jose, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

REVERSIBLE SOCKET WRENCH.—Egbert E. Masters, Sacramento, Cal. No. 536,754. Dated April 2, 1895. The object of this invention is to provide a tool which is adapted to fit and turn nuts or bolts having various sizes and shapes of exterior, and also to provide a socket which is adapted to receive a drill, screw-driver, countersink or other tool, with a means for advancing the tool independent of the socket. It consists of head-plates through which a hollow socket extends, said socket having a ratchet fixed to and turnable with it between the plates, and pawls pivoted upon each side, adapted to engage the ratchet teeth upon opposite sides, so that by engaging one, and disengaging the other, the ratchet may be turned in either direction, and a ring or sleeve surrounding the shank or handle and turnable thereon, said ring having a cam-shaped slot in the inner side by which either of the pawls may be allowed to engage with the ratchet while the other is disengaged.

LAMP STOVE.—W. R. Meyers, San Francisco, Cal. Assignor to W. W. Montague & Co., same place. No. 536,757. Dated April 2, 1895. The object of this invention is to combine with an exterior metallic casing, and a removable central draft lamp adapted to be suspended therein, an unperforated conical directing plate, either with or without a supplemental canopy, so that the air from beneath is directed over the upper part of the lamp body and concentrated toward the draft openings of the lamp proper, and the chimney therefor; and in conjunction with this is employed a sliding segmental reflecting door whereby the front of the stove may be opened or closed, and supplemental draft openings which are in use when the stove is thus closed.

CONNECTION FOR FLUSHING DRAIN-PIPES OF SINKS, WASHBASINS, ETC.—Fred. B. Vinter, San Jose, Cal. No. 536,769. Dated April 2, 1895. The object of this invention is to provide a simple and readily adjustable means for connecting a flushing or forcing pump with the drain or the waste pipe, whereby the latter may be cleansed or opened out when clogged, in an easy, thorough and effective manner, the work being done by one man instead of two ordinarily employed. The device consists of a plate or base adapted to fit within the vessel directly over the mouth of the drain or waste pipe, said plate or base having an internally threaded opening, and a washer or gasket under it to form a tight joint; means for securing and tightening the plate or base to its seat, and an internally threaded nipple fitted to the base and adapted to be screwed to the internally threaded opening thereof for the attachment of the hose of a force pump.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient to pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

PUMPS!

SEALED PROPOSALS

Will be received by the CITY OF SACRAMENTO, CALIFORNIA, until MAY 1, 1895, for furnishing and constructing

HIGH DUTY PUMPING ENGINES,

One (1) having a capacity of 5,000,000 gallons per twenty-four hours; the pump to be of the vertical triple expansion or cross-compound type.

The bid to include air pumps, valves, feed pumps, piping and all other appurtenances pertaining to a pumping plant, excepting boilers.

Steam-pipe connections must be made and furnished by contractor, also connections made and furnished to suction and mains.

The city to furnish concrete foundation for pump and build pump house.

Specifications may be obtained at the office of the City Clerk.

O. S. FLINT, City Clerk.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from David Croft, in the Gold Deposit mine, near Kelsey, El Dorado Co., to deposit tailings in an old hydraulic pit; from Wm. F. Coe, in the Railroad Placer Mine, near Placerville, El Dorado Co., to deposit tailings behind dams in Spanish Flat Ravine; from J. C. Day, in his mine near Georgetown, El Dorado Co., to impound tailings in an old hydraulic pit; from John A. Browles, in the Independence Mine, near Brownsville, Yuba Co., to impound tailings behind a dam in Letson Ravine; from Wm. Heming et al, in the Iowa Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jas. Ward & Wm. McDonald, in the Tiger Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jos. J. Hoffman et al., in the Hard Times Mine, Bath, Placer Co., to impound tailings in an old hydraulic pit; and from Wm. & Wm. J. S. Bacchi, in the El Dorado Placer Mine, Garden Valley, El Dorado Co., to impound tailings in ravine below the mine, gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, on April 22d, 1895, at 1:30 P.M.

TUBBS CORDAGE CO.
(A CORPORATION.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. ☞ Extra sizes and lengths made to order on short notice

611 and 613 FRONT ST., San Francisco, Cal.

Assessment Notices.

BRUNSWICK CONSOLIDATED GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley Mining District, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 20th day of March, 1895, an assessment (No. 8) of Two cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room 56, Nevada Block, San Francisco, California, or to the Treasurer, J. J. Halpin, 57 Broadway, room 87, New York City, State of New York, on or before the 20th day of April, 1895.

Any stock upon which this assessment shall remain unpaid in San Francisco, on the 20th day of April, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. STADTFELD JR., Secretary.

Office—Room 56, Nevada Block, San Francisco, California.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 20th day of March, 1895, an assessment (No. 18) of Ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 69, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

DELINQUENT SALE NOTICE.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Auburn, Placer County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 5) levied on the Eighteenth day of February, 1895, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amt.
Richard Chenery, Trustee	160	6,275	$125 50
Richard Chenery	17	5	10
Thomas May, Trustee	148	500	10 00
Thomas H. Gordon, Trustee	68	1,000	20 00
Thomas H. Gordon, Trustee	112	100	2 00
Thomas H. Gordon, Trustee	114	100	2 00
Thomas H. Gordon, Trustee	116	100	2 00
Thomas H. Gordon, Trustee	117	100	2 00
Thomas H. Gordon, Trustee	118	100	2 00
Henry Gilman	38	300	6 00
Henry Gilman	175	1,000	20 00
E. S. Harrison, Trustee	177	1,000	20 00
J. W. Winter, Trustee	161	250	5 00

And in accordance with law, and an order of the Board of Directors, made on the Eighteenth day of February, 1895, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the salesroom of S. P. Middleton & Co., No. 30 Montgomery Street, San Francisco, California, on WEDNESDAY, the Seventeenth day of April, 1895, at the hour of Two o'clock P. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

GEO. R. SPINNEY, Secretary.

Office—310 Pine Street, Room No. 28, San Francisco, California.

WANTED!

$2500—Wanted, a competent and honest quartz mill man, with above sum, to take half interest in custom quartz mill, permanent and desirable.

$5000—Wanted, a competent and honest quartz mill man (assayer preferred) to take interest in a custom quartz mill, chlorination works and a group of developed mines.

Both of these investments are safe and desirable, and invite investigation. For particulars, address

VAN DUZEN STEAM JET PUMPS
THE BEST IN THE WORLD.
Pumps any kind of Liquid. Always in order. Never clogs nor freezes. Fully Guaranteed. COST $7 AND UPWARD. Especially useful for Mines, Quarries, Pits, Wells, Clay Pits, Breweries, on Steamships, Ferryboats or any place where steam is available and liquid to be pumped. A full supply in stock. Address,
Jas. Linforth, 37 Market St., San Francisco.

Coast Industrial Notes.

—According to the new directories San Francisco's present population approximates 375,000.

—The total subscriptions of stock in the San Francisco and San Joaquin Valley Railroad to date aggregate $2,500,000.

—The eight per cent bonds of the Nevada County Narrow Gauge Railroad Company have gone from par to $110 bid.

—The Goldeu State and Miners' Iron Works have u contract for a 400-H. P. Corliss engine tor the Mutual Electric Light Co.

—Miller & Lux are putting in a large refrigerating plant at Butchertown. It is being built hy the Cyclops Machine Works.

—The Francis Smith Co. have about finished their $150,000 contract for twenty-two miles of pipe for the water company at Oakland.

—Right of way to put down an electric road from Goleta through Santa Barbara to Carpinteria, via Montecito, has been granted.

—The largest steel beam ever made on the Pacific coast was put in place in the new Parrott block on Market street last Sunday.

—The work of putting up the poles which are to be used to hold the wires that are to transmit the electric power from Folsom to Sacramento is about completed.

—A Southern Pacific trust deed recorded at Bakersfield transfers all of the company's property, including rolling stock, to the Central Trust Company of New York for $58,000,000.

—The uew steamer just finished by the Fulton Engineering und Shipbuilding Works for the Baronoff Packing Co., of Alaska, has been accepted by the owners and goes into immediate service.

—The Atlantic and Pacific roundhouse and machine shops at Winslow, Arizona, were burned last Wednesday. Eight locomotives were destroyed. The company's officials estimate the loss at $100,000.

—The Chino sugar factory consumes 1000 tons of sugar beets daily, and turns out 135 tons refined sugar per day. The factory cost $1,100,000. An oil pipe line is now building to supply it with fuel from the Puente wells. Three 17,000-barrel tanks will he used, and fourteen miles of 3-inch pipe.

Receiver Bird of the Tacoma Railway and Motor Company reports for February: total receipts, $4075.16; disbursements, $3117.09; net profit, $958.47. The net profit in January was $792.55, and in December $471.75. The assets of the company he reports to be $2,409,994.16, and the liabilities $25,200, unpaid interest on bonds.

—China and Japan are beginning to use more flour. England took 400,000 barrels less in '94 than in '93; China took 33,000 barrels more; all Asia 67,000 more, an aggregate of 698,878 barrels having been imported into that region last year. Japan is building flouring mills, and this year will probably see coast wheat cargoes sent to China and Japan.

—The largest individual wine deal ever made in the State was closed this week, F. Chevalier & Co., of this city, buying at 12½ cents per gallon from Dowdell & Co., of St. Helena, 400,000 gallons dry wine now stored at St. Helena. The wine has already been sold to prominent wine dealers in New York, where California wines are commanding better prices each year.

—Thomas Taylor, of Utah, who claims to hold Government pateuts for immense coal and iron fields in southern Utah, is in San Diego in the interest of the plan to build u railroad from Salt Lake to the bay of San Diego. His project is to turn over the property, which he considers worth $5,000,000, for stock in the company that would build a railroad between Salt Lake and San Diego.

—A San Joaquin valley land-owner has offered to place 200,000 acres of fertile land at tbe disposal of the New Eagland Colony Association on terms of interest only, for ten years, provided all the land suitable for cultivation in small tracts should be taken and occupied within two years. The object is to bring to California the native element of the Atlantic seuboard, who have been displaced by European immigration.

—A San Jose fruit-packing company has bought American rights for a new German method of preserving fruit in glass jars, with covers kept on by exhaustion of air in the jar. No solder is needed, and in opening the jar all that is necessary is to puncture the covers. Many million dollars' worth of tin plate is imported every year for canning fruit, vegetables and fish, and if the new process is successful this money will be spent here for glass jars.

—The Krogh Manufacturing Co., of this city, have recently bought the entire manufacturing plant of the San Francisco Tool Co., occupying the extensive brick building on Stevenson street numbering 11 to 19. The firm will continue the manufacture of water works pumps, centrifugal pumps, land reclamation and dredging machinery, water gates, etc. The new establishment will be conducted separately, and in addition to the company's works on Beale street.

—The Sacramento city trustees are having a great time in placing an order for pumps and pumping engines. Some months ago it was decided to buy, and proposals were called for, which, upon receipt, were referred to "a committee of experts on pumps," who, in due time, reported, making recommendation that a contract be given the Edward P. Allis Company, of Milwaukee, Wisconsin, for a 5,000,000 gallon vertical triple-expansion pumping engine for $18,300. At last Monday's meeting a motion to adopt the report and so award the contract was beaten by a vote of 6 to 3. The clerk was then instructed to advertise for new proposals.

(Successor to ADAMS & CARTER,)
AGENT FOR THE
FRUE ORE CONCENTRATOR,
132 MARKET ST.,
San Francisco, Cal.

Price of 4-foot wide	Plain Frue Vanner	$500, f. o. b.
" " "	Improved Belt Frne Vanner	600, f. o. b.
" 6-foot "	Plain Belt Frue Vanner	600, f. o. b.

GLADSTONE MINING COMPANY. FRENCH GULCH, Shasta Co., Cal.,
C. J. Clark, M. E., Gen'l. Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill. C. J. CLARK, Gen'l Supt.

IMPROVED CRAWFORD MILL.

The Cheapest and Best Mill for extracting gold from comparatively free milling ores. Requires one-third the water, and three-fourths the power of stamps. Costs less, is operated cheaper, and will save 20 to 40 per cent more gold. Average saving 85 per cent. Inexpensive foundation. No plates or screens. Wear and tear guaranteed not to exceed thirty cents per ton. Capacity ten tons. Full particulars,

MECHANICAL GOLD EXTRACTOR COMPANY,
47 BROADWAY, NEW YORK.

RISDON IRON WORKS.

Office and Works: Cor. Beale and Howard Sts., San Francisco.
Cable Address: "RISDON'S" San Francisco.

MANUFACTURERS OF

Red Rock, Goler and Summit Mining Districts in Kern County.*

The districts above mentioned are a part of the Mojave desert, in the northeastern part of Kern county. Tbeir placer deposits lie along the foothills of the Sierra Nevadas, cut through in places by wasbes emptying southward. Mainly confined to the north side of this line of hills is a series of beds of conglomerate, sandstone, volcanic tufas and lava-flows, dipping away from the range at an angle of 20° to 25°. The conglomerates at the base are free from volcanic pebbles; consisting of many kinds of rock; some foreign to tbe district, cemented and followed upwards by friable sandrock and volcanic beds. This is evidently a deposit on a marginal sea or lake bottom which has been elevated from the south and tilted northward. This elevation is greatest on El Paso peak, where it is nearly 5500 feet. Jaw Bone, Red Rock and Goler canyons, with lesser tributary canyons emptying southward, have cut these beds to a great depth. It is in these canyons and on the hills bordering them that the most of the placer gold is found. At tbe Summit, the easternmost district, the sandstone covers up the underlying metamorphic bedrock, and in the shallow washes draining southward from this sandstone the gold is found.

These facts all point to an original sea beacb on which the gold was collected by various means, decay of rock strata, wash of streams, etc., and that afterwards an elevation took place, followed by erosion of the present gulcbes, in which the gold has concentrated from the old conglomerate and sandstone. Little evidence has yet been found to show the original source of the gold. In the vicinity of Red Rock the porphyry is much mineralized over large areas, but it is not known whether it carries gold. Perhaps the richest gulch on the north side of the ridge, whicb between Red Rock and Goler is known as El Paso, is the Bonanza, which lies about two miles east of Red Rock. Here, as in the other gulches, tbe gold is found in the wash from the basal conglomerates and lava tufas. It is found not only in the gulches, but on the slopes of the hills several hundred feet above, and in the wash from the sedimentary deposits rather than from the crystalline rocks. In fact, only traces of gold are found in those gulcbes which head on the south side of the range or which lie above the conglomerates and other sedimentary formations. West of Red Rock no nuggets have been found. But little float quartz is found in the gravels, although small particles are often found adhering to the gold. Hundreds of claims have been taken up in the region about Red Rock, though but few of them have been worked. Water is needed to make these camps very successful, for although a few of the gulches are very rich, many are not sufficiently so to pay for using a "dry washer." There are said to be hundreds of acres which it would pay to sluice if water in sufficient quantity could be obtained.

The next gulch east of Red Rock is the Last Chance, which heads in El Paso peak and opens southwesterly across the range. Gold is found sparingly distributed over much country along this gulcb, and is more difficult to obtain, owing to the great depth of tbe wash in many places. In places in this gulcb and its tributaries

TABLE OF CONTENTS.

ILLUSTRATIONS.—Sandstone Cliffs near Red Rock, Kern Co.; Summit Camp, Ten Miles East of Goler, Kern Co.; Black Mountain, Between Goler and Red Rock, Kern Co.; Stratified Volcanic Tufa, East of Red Rock, Kern Co., 241. Columnar Basalt, Near Head of Kern River, Cal.; Basaltic Columns on Kern River, Cal., 245. Sectional View of Crawford Mill, 247.

EDITORIALS.—Red Rock, Goler and Summit Mining Districts in Kern County, 241. The Mint and Civil Service; Miscellaneous, 242.

CORRESPONDENCE.—The Prohibitive Seal Zone, 245. The Silver Problem; Shasta County Mining Notes, 246.

SCIENTIFIC PROGRESS.—Terrestrial Helium; A New Blasting Powder; Height of Clouds, 248.

MECHANICAL PROGRESS.—How an Ax is Made; Rating of Feed Water Heaters; Some Comparisons Bearing Upon Engineering Construction; Not Following Instructions; Bridges of Old Rail, 249.

ELECTRICAL PROGRESS.—Large Guns as Magnets; A Tremendous Light, 257.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 250-51.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 254.

MISCELLANEOUS.—Concentrates; Personal; Obituary, 243. Characteristic Features of California Quartz Veins; Very Pure Gold, 244. Arizona Prospectors; Fares and Prices at Cariboo, 245. Books Received, 246. The Crawford Mill, 247. The Columbian Exposition Medals; De Lamar in California; Metal as a Building Material; Luminous Paint, 253. Notices of Recent Patents, 244. Coast Industrial Notes, 245

THE growing sentiment in favor of remonetization of silver shows that the Nation is at last realizing that it is not, as has been charged, a simple effort of silver producers to make a market for the product of their mines, but a prime necessity in national prosperity.

THE contemplated affiliation of the Technical Society of the Pacific Coast and the Mechanics' Institute will not take place. The latter institution was not averse to the idea provided the Society would merge itself into and be absorbed by that organization; but the desire of the Technical Society to preserve and maintain its separate autonomy made the idea inexpedient. The most cordial relations exist between the two organizations; and each will continue separate and independent as before.

FOUR WEEKS AGO extended notice was given the famous case of the Tyler vs. the Last Chance Mining Co., wherein the Secretary of the Interior had given a point in favor of the former on a side litigation, the main issue being at the time in the United States Supreme Court. That tribunal this week reversed the decision of the U. S. Circuit Court of Appeals, and remanded the case for a new trial. Had the Court decided in favor of the Tyler, it would have been final. The attorneys of the Last Chance think that this last decision in their favor is final, as the Court of Appeals, to which the case goes back, must decide in their favor, but the Tyler attorneys say the final result will depend upon the nature of the instructions sent back by the Supreme Court. So far, the Last Chance owners have spent $125,000 in litigation; the Tyler people nearly as much more, and the end is not yet.

EXTENDED REFERENCE was recently made in this column to the new London Sulman-Teed process for the extraction of gold by the agency of bromo-cyanogen, it being claimed by its inventors that oxygenation was unnecessary and that the accelerating effect of the bromo-cyanogen was such as to bring about in a few hours what required days by the ordinary cyanide process, and was also similarly claimed that the most rebellious of gold ores could be satisfactorily treated by this new process. Two companies have been formed in London, England—"Sulman's True Gold Recovery Syndicate," and "The Gold Ore Treatment Company," each with a large nominal capital. The former has been absorbed by the latter upon the payment of £5000 in the shape of 5000 £1 shares of hitherto unissued capital of The Gold Ore Treatment Co. The officials of this company claim that they have very good prospects for immediate success and that their stock is now worth £2 5s per share.

The Mint and Civil Service.

When the Civil Service law was passed, it was a great surprise to the people that the Mints of the United States were not made subject to its provisions. A word from Mr. Burchard, the Director, would have saved that great service from the evils of the party spoils system; but he has been excused on the ground that he was at that very time fighting to be continued as Mint Director, and had no time to bring this matter to the attention of Congress.

The Mint in San Francisco handles from thirty to fifty millions of dollars every year. The gold and silver bullion sent to that institution for coinage is in all sorts of crude conditions, and some of it is subjected to twenty or thirty operations before it comes out in standard coin. In these various operations hundreds of persons must handle it. Honesty, conscientiousness, large experience and technical knowledge are needed on the part of those who have to do with mint work, in its various processes of melting, assaying, refining, ingot making and coining. Why should the letter carrier be protected by Civil Service laws, while persons in the Mint have no protection?

Every Mint superintendent in San Francisco for the last twenty-five years has lived a burdened life, on account of the demands of Congressmen and political bosses. The real work of the superintendent has to be performed very largely by his chief clerk. Judge Lawton, H. L. Dodge and Mr. Burton had some independence; but they could not always do as they wished. Senators Sargent, Stanford and Felton were the powers behind the throne. They had but to say to the superintendent of this or that man in the Mint, "He must go," and he went. No matter how efficient or how long tried, he must go, and his place was filled by some politician who could do good service for the party, and for the Senator who had placed him in the Mint.

Each new superintendent, instead of familiarizing himself with the financial conduct of the Mint, studies the pay roll, consults his political backers, the local or interior bosses of the party, and then begins to wield his official axe. In the course of a year or two he has turned out all he can well discharge, and then begin his own troubles. Two or three thousand men and women asked to be appointed. Only one hundred or perhaps one hundred and fifty received appointments. For every lucky applicant there are fifty who fail to get in the service; and now they hate the superintendent. Under the spoils system he has done his best. But what a failure! What an army of enemies rises up to curse him up hill and down! Looking back, we can all remember how Gen. La Grange raised an army of political foes; how Henry L. Dodge had to withstand the assaults of a Congressman because there were not offices enough in the Mint for the friends of Mr. Page; and now the present superintendent—Mr. Daggett—is having the lash laid on his back. It seems that he had political ambitions, and they tell us that he used the Mint to forward his aspirations. Under the spoils system it would be strange if he did not try to favor himself a little while helping others. Gen. Dimond had an ambition also to be Governor, but Mint patronage buried him. The bosses could not get places enough, and so an army of disappointed ones are ready to down him. He suffered. Mr. Daggett is now the object of their hatred. It is as it has been and will be until service in the Mint shall depend upon honesty, efficiency and good conduct instead of political service.

Another vicious result of the spoils system in the Mint is its demoralizing influence on the men there employed. So long as they have the backing of some boss or Congressman, they feel secure, no matter how they deport themselves. The superintendent himself or the coiner or assayer cannot hold the man to the same rigid rule as others are held because he has a pull. Mint officers could give some information on this subject that emphasizes this statement.

The insecurity which one feels in the Mint service when a new superintendent starts the official guillotine unfits him for work. He becomes inefficient, and time that should be given to the Government is spent seeking to get some influence to prevent his removal.

The tyrranical power of the spoils system is wielded with telling effect just before a general election. In spite of the law which forbids political assessments to be made upon people in the Mint, the superintendent decides for each employe what he should give to run the campaign, and contrives to let it be known that if it is not paid he will be dismissed.

The superintendent does not assess openly, but for all practical purposes he might as well do so. The law is a dead letter. The poor man who works for $75 or $100 a month, and earns it, who needs it for his family, has no option. He is told that the committee has put him down $50 for the party expenses. He pays it, swears about and denounces it, but all the same he pays it in order to save his position. The tens of thousands raised in this way out of the Mint and other Government institutions, through the committees, is a big fund manipulated for the benefit of the bosses.

The San Francisco Mint has been used by the spoilsmen and bosses for a quarter of a century, as no other Mint in the country has been used, unless it be the Mint at Carson. Andrew Mason, a life-long Democrat, has had charge of the New York Assay Office for a third of a century, through all administrations. He has never allowed politics to run his office, and when the bosses have asked him to allow the employes there to be assessed he is said to have a waste-basket for all such letters.

The Civil Service law should be extended to the San Francisco Mint. It would promote efficiency, tend to economy, exalt the character of the service, and would be a boon to its superintendent. It would make him a superintendent in fact, be a welcome change to all the officers of that institution and a great benefit to the people.

THE Sacramento *Record-Union* has begun a new crusade against hydraulic mining and daily devotes considerable space to opposing the only present paying industry in the State. Our Sacramento contemporary argues that hydraulic mining is destructive to the State, demoralizing to those who so mine, immoral in its workings and tendencies, and a bad thing generally. These are matters of opinion, and, of course, the *Record-Union* has a right to be wrong. But it has no right to make statements that are untrue. It publishes editorially, and reiterates a great many things, in ignorance or defiance of the facts; it misquotes history, distorts statements, garbles records, and throughout evinces more of a desire to be false and malicious than fair or candid. Those utterances are in painful contrast to its usual dignified and courteous manner, and can only arouse a feeling of regret that a journal which has so often reproved reckless mendacity in others should descend to such low levels of journalism itself. The cause it champions must indeed be a weak one when it fails to cite argument or truth, and contents itself with utterances that are in direct opposition to the facts and apparently made only to foment prejudice and antagonize interests that are gradually and amicably uniting. As for answering the *Record-Union's* recent statements, they have long since been completely and effectually answered by the logic of events. It is hoped that its madness is but temporary. If it will drop direct falsehood and manifest exaggeration, and deal with this subject as a decent journal should, its adverse comments will receive attention and answer, which its present ravings neither deserve nor require.

NOT content with South African opportunities for investment in mining shares or snares, the eager Parisian public is at present embracing another golden opportunity. The auriferous black sands of New Zealand also engage favorable attention, and a Lieutenant Bassett tells his mercurial French friends that on a capital of £70,000 they will make an annual profit of £86,000 for ten years. The account naively says that "Monsieur Bassett has hit upon an ingenious idea of separating the iron sands from the gold by magnetic attraction." The hundreds who long ago hit upon the same idea here will view "Monsieur Bassett's" New Zealand progress with considerable interest.

Concentrates.

THE Bonanza mine near Baker City, Or., cleaned up $7,500 in gold in March.

STOCK shares in the DeLamar mine of Idaho are selling in London at 31 shillings.

THE Taylor mine, Placer county, is arranging to put in another 40 stamps, making 90 in all.

A RICH ledge of free gold is reported from the Ackerman mine, three miles from Auburn, Cal.

THE Poorman, at Boise, Idaho, has 180 men on its pay roll, the monthly disbursement is about $20,000.

THE annual meetings of the Goleta, Montecito and Sterling Mining companies have been called for May 8.

THE Rock Creek Mining Co. have put in a Hammond 10-stamp mill at their mine near Baker City, Or.

THERE are so many $20 gold pieces in Rossland, B. C., and so little change that silver coinage is at a premium.

SPOKANE, WASH., has a laudable desire to have sampling works and a Government assay office established there.

THE Spanish mine at Washington, Cal., is to be opened by Fred Bradley, who will have a new mill erected on the property.

HALF the able-bodied men in Douglas Co., Wash., are reported to be getting outfits ready to rush to the Methow mines.

THE Reward Gold Mining Company of Nevada county has levied an assessment of 2½ cents per share, delinquent May 10.

PRELIMINARY arrangements are reported for amalgamation of all the miners' unions in Colorado, Wyoming, Utah and New Mexico.

A NEW rate of $6 per ton on ore from Spokane to Everett, and $6.50 to Great Falls, Mont., has been put in effect by the Great Northern.

THE Idaho Springs, Col., *Gazette* says the recent reduction in the price of smelting around there means all the way from $4 to $10 per ton to the miner.

AS NEAR as can be ascertained, it is believed that there are now 17,000 men engaged in mining in the three States of California, Oregon and Washington.

THERE is talk again of the starting of a smelter in Prescott, Arizona. This has been talked of off and on for years, but the present talk sounds business-like.

RICHARD PHELAN, superintendent of the Gold Ridge mine, tells the Grass Valley *Union* that the company intends to erect a 40-stamp mill some time this summer.

A MICHIGAN Bluff, Cal., correspondent says that Chinamen are again employed at the Hidden Treasure mine at Sunny South—about 25 of them at $1.50 per day.

NEW hoisting works, etc., are to be bought by Supt. Nibel, for the Brunswick mine at Nevada City, the recent strike at the 800-foot level justifying the expenditure.

BAKER CITY, Or., men report that the Belleville mine will soon be sold to Eastern parties for $200,000. The full development of that mine would put 200 men to work.

AFTER paying $500,000 in assessments the Le Noria Silver Mining Company of Mexico with head office in Pittsburg, has passed into the hands of W. L. Munstin of that city.

UNDER a law passed by the Arizona legislature, a heavy penalty is attached to the "salting" of a mine for the purpose of deceiving any one as to the value of the ore it contains.

J. WHITE of Baker City, Or., has a contract for constructing a water ditch from Jordan creek to the Chicago Company's placer mines on Burnt river, a distance of two and a quarter miles.

OREGON prospectors report a good gold country between Burat river and the bend of Snake river, about twelve miles north of Huntington, and say that free-milling gold ledges are plenty.

A DISPATCH from Weaverville, Trinity Co., states that a wagonload of Japanese laborers, going to Big Bar to work near there, were stopped at Junction City by miners and sent back.

A COLUSA COUNTY MAN writes to the *Examiner* for information as to where he can get a needle "used by miners for the discovery of gold." A haystack would be a suitable place for him to look.

THIRTEEN Comstock miners leave here on the 24th for the Candelaria mine, San Demis, Durango, Mexico, in the employ of S. Treglone who has a $30,000 contract to run a 2,500 foot tunnel there.

THE *Sentinel* says for the month ending March 31st, more than $1,000,000 pounds of sulphurets were loaded at Colfax, consigned to the Selby Smelting Works in this city and to Everett, Washington.

STOCKS were quoted in San Francisco, June 15, 1866, as follows: Chollar-Potosi $200, Imperial $112.50, Gould & Curry $750, Hale & Norcross $960, Savage $1010, Belcher $195, Yellow Jacket $695, Ophir $345.

THE Carson River Placer Mining Company that works the dredge near Dayton, Nev., recently illustrated herein, started up its plant last week. About twenty men are employed, and it is said that the results are highly encouraging.

THE County Clerk of Coos county, Or., says the *Coast Mail*, received a United States patent to record, last week, conveying 125,409, 45-100 acres of land in that county to the Oregon and California railroad company.

THE four-stamp quartz mill of John Sipp & Co., near Blue Canyon, Cal. has been crushing ore all winter. They are working what is familiarly known as the old Red Stone quartz ledge, and will soon put on more men.

THE Orr Extension Ditch Company of Reno, Nev., has levied an assessment of $15; delinquent May 26. The North Banner Consolidated Tunnel Mining Company of Nevada County has levied one of 3 cents, delinquent May 14.

LAND COMMISSIONER LAMOREAUX has issued instructions to the mineral land surveyors in Montana and Idaho, recently appointed by the President, to organize by the 25th of this month and be ready for business by May 1st.

MINING reports from about Yale, B. C., show considerable activity there. Yale bar, across the Yale, is being worked by a company with plenty of capital. Preparations are making to work the Siwash creek mines. At the mouth of the canyon white men are rocking out from $3 to $10 per day.

A CONFERENCE of Tasmanian miners has resolved that every prospector should have a life interest of 1 per cent of the net returns of minerals won from any mine or mines he may have discovered, such interest not to be transferable.

THERE has been no change in the law relative to the regulation $100 worth of labor for improvement on mining claims. So claim holders have till December 31st, 1895, inclusive, to do their assessment work for the current year.

IT is said on good authority that a party of French capitalists have gone to Quesnelle river to look at mining claims owned by the Seattle company, says the Victoria *Colonist*. If the mines are as represented a transfer will take place.

DR. LANGHAMMER is investigating the prospects of the St. Helens mining district in Lewis county, Wash. He represents Pabst, the millionaire brewer of Milwaukee, and other eastern capitalists, who have options on properties in that district.

THE old pump at the 900 level of the Providence, Nevada Co., mine has broken down and will have to be replaced with a new one. In consequence of the break-down and the necessity of changing the pump, some of the miners have been laid off temporarily.

SUPERINTENDENT PARKS, of the Kennedy mine, says that the account in an Amador paper last week of a half ton of rock from the Kennedy going $130,000, is a no such thing. While the Kennedy has rich ore they are not "refining it at the chlorination works."

THE annual gold boom has struck the Copalis, Wash., beach. Ten tons of sand were shipped here recently, and if that amount of sand turns out as much mineral in proportion as one ton did that was shipped here some time ago, 20 or 30 machines will be shipped up immediately.

FIFTY men are at present working in the West Harmony drift gravel mine, Nevada Co. The fifteen-stamp mill runs steadily seven days a week. Superintendent Gassaway considers that by careful mauagement gravel going eighty-five cents to the car can be made pay.

THE Denver commissioners have voted $100,000 in aid of the mining and industrial exposition to be given there. The city will appropriate $75,000 or $100,000, and Congress will be asked to appropriate $250,000. Eighty acres in and around the city park have been chosen as a site for the exposition.

AT the annual meeting of the Champion Mining Company the following officers and board of directors were elected: Gus Kartschoke, president; H. Mohr, vice-president; J. S. Ott, J. Moock, J. Assion, Joseph S. Schuster, Dr. A. Wilhelm, Frederick Zeitler, superintendents; J. F. Holling, secretary.

AN item is traveling around to the effect that the United Verde, Jerome, Arizona, "produces annually 1,500,000 ounces of gold, 7,000,000 ounces of silver, 9,000,000 pounds of copper." The copper proposition is all right, but the other figures would be nearer the truth were the three right hand ciphers dropped.

AT Gem, Idaho, the Frisco mine is running with about 100 men, sinking and crosscutting fine ore. At the 200-foot level a 70-foot vein of galena ore was uncovered. The Gem is now sinking, doing considerable development work, and making repairs. They expect to begin active operations shortly with a full force of men.

ADVICES from Osborn, Idaho, are to the effect that trouble is feared between the miners' union of the Cœur d'Alenes and the manager of the Bunker Hill and Sullivan mines, "should he decide to start up the mines or even openly offer to do so on the company's proposed scale of $3 per day for miners and $2.50 for shovelers."

A LONDON cablegram says the appeal of the Cassel Gold-Extracting Company of Glasgow from a decision of the lower court against the validity of its patent for the cyanide process of treating refractory ores has been dismissed, but that, by an amendment of the specifications of the patent, the defect held by the Court to exist can be cured.

THE Marlow Mining and Development Company has incorporated at Sacramento, "to do general mining and to buy and sell water for mining purposes in Tuolumne county." Capital stock, $300,000. Directors—J. Graham, Forest Home; F. J. Cross, Tuttletown; C. E. Weinrich, A. P. Seheld, T. L. Enright, W. W. Andersen and G. D. Stewart, Sacramento.

TWO EXPERIENCED MINERS went to the old Manzanita mine, near Nevada City, on Tuesday with pans and pushed over a large boulder, beneath which was a small quantity of gravel. The first panful of dirt yielded $40; the second, $50; while they secured $8 from the tailings. The *Tidings* says they would like to find some more boulders waiting to be pushed over.

COLORADO papers say that smelters are preparing for a great increase in the visible supply of silver, which has been exceedingly scarce for a year or more. They have agents in all the mountain towns, and they report that miners of silver are returning to their properties that were shut down after the slump, and are preparing to take advantage of the present advance.

THE Deadwood *Pioneer* says the Holy Terror deal has been consummated on the following terms: The Chicago parties deposit $25,000, sink the shaft 300 feet on the ledge, and also deposit the amount of gold taken out while sinking. If, when the shaft has reached a depth of 300 they decide to buy the mine, they pay the owners $125,000. If not, they forfeit the $25,000 deposit and all the mineral taken out while sinking.

OF Cripple Creek, Colorado, *Ores and Metals* says: A mining man who paid $9.75 a ton for treating his ore in Denver in combine days, now pays $5. The stamp mill ore treated in the district averages $10 per ton caught on the plates and concentrates and that treated by chlorination averages $30. It is intimated that the reduction works, recently completed at Florence, are not suitable for the treatment of Cripple Creek ores.

WHEN Col. F. R. Morton was killed at the Cananeas property in Sonora, Mexico, he left some money in the bank at Nogales, Arizona, which has been administered upon. E. Self, assayer there with Col. Morton, will push work on the mine. The terms of the sale of the property are understood to be $50,000 in two months, with development to be done in the meantime to the extent of $300 per month. The property belongs to Mrs. Pesquera. About $20,000 has already been paid on the property. The buyers are the Heinz Brothers of New York, heavy copper owners in Montana. The property was abandoned at the time of the killing of a superintendent twelve years ago.

THE Nevada Silver Mining Company, with headquarters in Chicago, and mines in Tem Pahute, have issued bonds on the property to the amount of $1,050,000 in five series, bearing interest. The bonds are in amounts from $500 and upwards. The property consists of a group of seven silver mines, and are generally regarded valuable. This system is a new departure in the manipulation of mining, and its results are looked forward to with considerable interest.

THE official returns of the ore worked and the bullion produced at the Nevada mill for the Chollar Mining Company for March shows that 820 tons were worked, yielding bullion of the gross assay value of $19,661 28. The cost of reduction was $4,920. The net proceeds in bullion were valued at $12,-277 14. The average assay of the ore per ton was $27 76. The gross average per ton was $23 98. The net average was $17 98 per ton. The mill worked the ore up to 89.2 per cent. of its assay value.

THE following is from last Wednesday's Sacramento *Bee*: "The Executive Committee of the State Anti-Debris Association met in this city yesterday afternoon. It was reported that Heustler's dam, near Columbia Hill, Nevada county, had broken, and that quantities of debris were passing through the break and down the river channels. The break is forty feet wide. The North Bloomfield dam, it was reported, had also broken, with the same result, the debris which it had been holding back now passing down into the Yuba river."

THE Madera, Cal., *Mercury* says: Tax Collector L. W. Krohn brought with him from Coarse Gold about $600 worth of gold dust. He stated that the gold was brought to his store by squaws and given to him in exchange for provisions and clothing. The gold was found in the gullies about Coarse Gold. This is the only kind of currency the Indians possess. Whenever the Indians want some food or clothes they go out into a gulley and scrape up a little gold which has been washed down by the streams or by the rains. Mr. Krohn says that the statement that gold can be picked up about Coarse Gold is literally true.

REGARDING the Comstock, last Wednesday's Virginia *Enterprise* says: "The situation in the Con. Virginia, which was fully described in the last letter of Superintendent Lyman, is creating much enthusiasm in mining circles. So far as known the new ore body which is being followed and which is apparently improving as progress is made on it, is not interfered with by any old workings. There is now enough ore in sight to warrant starting the mill soon, and the proceeds from the new body will reach a very respectable figure. There is little news to be obtained from the other mines on the lode."

DIRECTOR OF THE MINT PRESTON has received a report from Andrew Mason, Inspector of the United States Mints, stating that the actual gold shortage in the Carson Mint is $75,499 72. No further shortage is expected to be found, as the amount stated is the result of nearly two months' careful investigation. John F. Jones, the assistant melter and refiner, who is under arrest in connection with the shortage, was suspended from duty April 6th and will be dismissed from the service. Other arrests are expected to follow. The bond of the melter and refiner is $20,000 and of the assistant $10,000. It is probable the Carson Mint will be closed permanently.

W. BROWN, manager and principal owner of the Volcanic Mountain claim, on the north fork of Kettle river, Montana, says the tunnel which is being driven by himself and assistants to tap the vein on the claim is now in a distance of 300 feet. If they are successful in striking a large body of ore their reward will be represented, not by hundreds of dollars, but by hundreds of thousands, as Mr. Brown considers that the day they strike the ledge with the tunnel this same claim will be worth to them a million dollars. This mode of developing their property is certainly a departure from the general methods adopted by the average run of prospectors.

—They do things in Australia that seem queer from a California standpoint. The following is from the *Australian Mining Standard*: "Mr. John Freeman, a mining manager at Wandiligong, has had a decidedly unpleasant experience of the power of law costs. Having spent two years in experimenting with the cyanide process of gold extraction, Mr. Freeman was summoned to tell the South African Commission, now sitting in Melbourne, what he knew of the matter. Mr. Freeman was willing to do this on payment of £150; and, as he stated himself, the information "was cheap at the price." The Commission, however, took another view, refused to pay the money, and applied to the court to compel Mr. Freeman to unbosom his cyanide secrets. Mr. Justice Hodges ordered Mr. Freeman to gaol if he persisted in his refusal to give evidence, and directed him to pay the cost of the proceedings. The judge takes the view that even if his research cost Mr. Freeman time and money, he is bound to give the administration of justice the benefit of it."

Personal.

PROF. POTTER of the Washington University, president of the Mining Engineers' Association and president of the St. Louis Smelting Company, is examining mining property in Inyo county.

W. W. WAGGONER has accepted the position of assistant engineer for the California Debris Commission vice W. B. Storey, Jr., resigned.

H. A. WOODS, of the Woods Investment Co., who has been in Lower Cal. for some weeks, has gone to Seattle, Wash.

Obituary.

J. W. HOWELL, foreman of the Copper Queen Con. mine at Bisbee, Arizona, died last week.

PROF. JAMES DWIGHT DANA, author and scientist, of Yale University, died at New Haven, Conn., last Sunday, in the 82nd year of his age. In 1837 he published "A System of Mineralogy," a work of high repute. He accompanied Lieut. Wilke's exploring expedition in 1838-42. During succeeding years he wrote a number of works on geology, mineralogy and kindred subjects. For many years he published the *American Journal of Science and Art*. He was a member of many learned societies in this country and in Europe.

Characteristic Features of California Gold-Quartz Veins.

NUMBER III.—CONCLUDED.

Read before the Geological Society of America by WALDEMAR LINDGREN, December 29, 1894.

Along the mother lode the altered serpentine has been variously interpreted. Whitney inclined to the belief that the vein represented a stratum of silicified dolomite, a theory that has not been supported by more detailed investigation. Fairbanks, who some years ago carefully examined the mother lode, considered it at first as vein matter deposited in open fissures, but regarded it subsequently (as the needed, once open space would manifestly have been too large, in places several hundred feet) as an altered, coarsely crystalline basic rock. The latter theory, while nearer the truth, is unnecessary. A careful investigation will not fail to disclose the fact that the mixture of carbonates and mariposite is nothing but an altered serpentine, and abundant transitions may be found to prove this. A locality showing this plainly is the App mine at Quartz mountain, Tuolumne county. This conversion is not astonishing when the facility is considered with which the serpentine is decomposed by carbonated waters into magnesite and chalcedonic quartz. Experiments by C. Doelter show that while at ordinary temperature and pressure water containing carbon-dioxide will, with simultaneous decomposition and formation of carbonates, dissolve 0.3 per cent orthoclase and 0.5 per cent oligoclase, serpentine will be dissolved at the rate of 1.24 per cent.

The large bodies of decomposed rock previously referred to as containing impregnations of auriferous pyrites and rarely free gold are in many respects interesting. In the ferruginous outcrops the iron pyrites is usually converted into ferric hydroxide and the gold set free; the whole mass can then sometimes be profitably mined and milled, though it is of very low grade. Veins and seams of quartz are often entirely absent in these impregnated zones. In the cases which have come under my observation the action on the rock is much the same as in the decomposed wall-rocks of the veins—that is, there is an abundance of carbonates and iron pyrites in sharp edged, little crystals. While there is abundant evidence of replacement by carbonates, I have not yet seen anything proving a replacement by quartz, though the possibility of such a process cannot be denied. However, in these deposits the action of the solution on the rock-forming minerals must have produced much free silica in solution and probably also much sodic silicate; in fact, there are in these deposits occasional masses of singular, grayish quartz very different from the ordinary vein quartz and probably partly chalcedonic. This quartz often contains iron pyrites in small scattered crystals, and appears to represent in part residual masses from leaching, in part deposition from supersaturated silicious waters. H. W. Fairbanks has recently described two deposits in El Dorado county, the Big Canyon and the Shaw mines, as showing in marked degree the replacement of the rocks by silica. Though the latter mine was not worked during my examination of the Placerville sheet. I have, through the kindness of Mr. H. W. Turner, had occasion to examine an excellent suite of specimens, lately collected. The vein is partly in black slate, partly in a feldspathic dike. Both rocks contain an abundance of stringers and seams of quartz and calcite, but I fail to see any evidence of the wall-rock by the former mineral. On the contrary, the porphyritic dike is to a very marked degree converted into carbonates in the vicinity of the veins. Regarding the Big Canyon mine, I have seen only two specimens of greenstone impregnated by pyrite from this mine, and collected by Mr. H. W. Turner. These specimens show carbonization to a considerable extent, but no evidence of replacement by silica. It is not intended to deny that such a process may take place, but only to point out that it is something requiring more and more detailed investigation. Calcite is found pseudomorphic after an enormously large number of minerals, while pseudomorphs of quartz after other minerals are much less common.

The country rock altered to carbonates, standing in strong contrast to the vein filled nearly exclusively by quartz, affords a much-needed key to the genetic processes of the deposits. It shows, first, that besides silica, the water circulating in the fissures contained large amounts of carbon-dioxide, as well as dissolved calcic carbonate. It certainly contained sodium as carbonate taken up from the feldspars of the adjoining rocks, probably also as silicate and chloride. It further contained sulphur, in what form is not certain, but most probably as sulphuretted hydrogen or as sulpho-salts. The presence of large quantities of sulphates does not appear probable.

Waters of this composition, containing abundant carbon-dioxide, are only known in nature as ascending, usually hot springs. The process of deposition took place as follows:

At first the carbonated waters began to act with great energy on the soluble minerals in the wall-rocks of the fissures, converting them more or less completely into a mixture of carbonates, potassium-micas and pyrites, adding calcium-carbonate and sulphur, probably also potassium, to them, and abstracting sodium. Finally, this process being completed, and the walls usually coated with crystals of carbonates, the formation of the latter ceased, and in this surrounding of carbonates the silica now began to be deposited, and with it the gold and the rest of the metallic sulphides.

A most interesting question in connection with this subject is, why the walls should, to such a large extent, act as a separating barrier for the gold and most of the sulphides. Mr. G. F. Becker, in discussing the quicksilver deposits of the Pacific coast, has suggested that this may be due to an osmotic action, transmitting through the septum only the chemically active solutions.

Admitting that the gold-quartz veins were deposited by such mineral waters, the next question is, in what form the gold and other metals were in solution. While not intending to enter into a detailed discussion of the difficult problems associated with the question, I would like to call attention to a few general facts connected with them. Gold is soluble at 200° Centigrade in a 10 per cent solution of carbonate of sodium to the extent of 1.33 per cent (Doelter), while silver is hardly attacked. Silicates of alkalies dissolve gold at 250° Centigrade to the smaller extent of 0.101 (Doelter and Liversidge). Besides, gold is more or less soluble in a great many other salts (T. Egleston). G. F. Becker has shown the solubility of gold in alkaline sulphides, and the solubility of the sulphides of Hg, Fe, Cu and Zn in either sodic sulphide, sodic sulph-hydrate or sodic carbonate, partly saturated with sulphuretted hydrogen. Silicate of gold, the existence of which was first suggested by G. Bischof, has been frequently mentioned as probably contained in mineral waters; but it should be borne in mind that the existence of this salt has never been proved. It appears that the mentioned facts are sufficient to show that the mineral waters, once circulating in the quartz veins of California, may easily have held gold in solution. It seems of questionable use to speculate on the particular combination in which the gold is contained in the water, for, according to the views of modern chemistry, watery solutions, when sufficiently diluted, contain the solids in a state of disassociation, so that it is uncertain whether salts of gold could exist as such in the always much diluted natural solutions.

The precipitation of the solids contained in the solution could have been brought about by many means, such as diminution of pressure, dilution, etcetera. The reducing influence of carbonaceous slates, so often maintained as the probable cause of the precipitation of the gold, appears of questionable importance. Veins entirely in massive rocks and far away from any sedimentary areas show too much similarity with those in such areas to attribute a paramount weight to this argument.

There are certain interesting analogies between the gold-quartz veins of the Sierra Nevada and the quicksilver deposits of the Coast ranges. In the Sierra Nevada the association of minerals is native gold with predominating quartzose gangue; carbonates in the wall-rocks, next in importance, iron pyrites with smaller quantities of the minerals of copper, lead, zinc, arsenic, and antimony; quicksilver ores are occasionally present. In the Coast ranges we have quicksilver in predominating quartzose, and to some extent carbonate gangue; next in importance, iron pyrites with smaller quantities of copper, antimony, arsenic, and nickel; gold is very commonly present.

Regarding the rocks adjoining the deposits, Mr. Becker says they "have in many cases been greatly modified. Metamorphic rocks often appear to have been converted into or replaced by more or less dolomitic carbonates by the action of solutions. * * Both serpentine and the metamorphic rocks seem to be subject to this conversion."

Containing a similar association of metals, similar gangue and similar altered country rock, it seems justifiable to express the conviction that similar mineral solutions have circulated in both classes of deposits; and, in fact, the still abundant thermal waters found in intimate connection with the ore deposits in the quicksilver region closely correspond in character to the inferred composition of the once existing hot springs of the gold belt. They all show free carbonic acid, as well as abundant carbonates (sodic, calcic and magnesic); silica is always present; usually also sulphuretted hydrogen or alkaline sulphides.

Carbonatization of the wall-rocks of fissure veins has neither been described by A. v. Groddeck nor F. v. Sandberger in their researches, though the former has found abundant sericite in many. The wall-rocks of the Comstock lode, according to Mr. Becker, are rich in iron pyrites, but do not contain much carbonates. J. H. L. Vogt has shown that along certain veins of Norway the granite and gneiss are altered to products resembling the "greisen" of the tin deposits.

Regarding the origin of the hot, auriferous solutions which have produced the gold-quartz veins it is best, at this stage of our knowledge, to speak with great reserve. Even the results of assays or analyses of country rock must be received with the greatest caution, to make sure that the percentage discovered is primary constituent and not later impregnation. It is not to be denied that many reasons speak strongly against a derivation from the surrounding rocks. Thus, for instance, the diorites of Nevada City and Grass Valley contain an appreciable amount of barium, and still there is no trace of barite in the veins of these localities. In another instance the diabasic rocks of the same region contain copper, and yet the gold veins passing through these rocks are remarkably poor in copper minerals.

In discussing this difficult question there are several broad facts which must be borne in mind:

First, that the gold-quartz veins throughout the State of California are closely connected in extent with the above-described metamorphic series, and that the large granite areas are almost wholly void of veins, though fissures and fractures are not absent from them.

Second, that in the metamorphic series the gold-quartz veins occur in almost any kind of rock, and that if the country rock exerts an influence on the contents of the veins, it is, at best, very slight.

Third, that the principal contact of the metamorphic series and the granitic rocks is in no particular way distinguished by rich or frequent deposits.

It is further apparent that gold deposits have been formed at different periods, though by far most abundantly in later Mesozoic times. Some of these later veins may have been locally enriched by passing through earlier impregnations in schist or old concentrations in the sandstones and conglomerates of the metamorphic series, the gold contents of which have, however, only been proved in isolated cases.

These considerations, though involving many most difficult questions, strengthen the belief that the origin of gold must be sought below the rocks which now make up the surface of the Sierra Nevada, possibly in granitic masses underlying the metamorphic series.

Summary. — The auriferous deposits extend through the State of California from north to south in an irregular broken line.

The gold-quartz veins occur predominately in the metamorphic series, while the large granitic areas are nearly barren. The contact of the two formations is not distinguished by rich or frequent deposits.

The gold-quartz veins are fissure veins, largely filled by silica along open spaces, and may dip or strike in any direction.

The gangue is quartz, with a smaller amount of calcite; the ores are native gold and small amounts of metallic sulphides. Adjoining the veins the wall-rock is usually altered to carbonates and potassium-micas by metasomatic processes.

The veins are independent of the character of the country rock, and have been filled by ascending thermal waters, charged with silica, carbonates and carbon-dioxide.

Most of the veins have been formed subsequent to the regional metamorphism which affected the auriferous slates and the older igneous rocks associated with them, and also subsequent to the granitic intrusions which closed the Mesozoic igneous activity in the Sierra Nevada.

Very Pure Gold.

To-day, says the Grass Valley, Cal., *Tidings* of the 10th, we were shown a certificate from the United States mint at San Francisco, dated December 8th, 1887, and it was the return of 6.32 ounces of gold dug from the ground near Rough and Ready. The gold sent was in amalgamated cakes and the above was the weight of the cakes before melting; after melting 6.09 ounces, the fineness thereof was 992¼, the sum being $124.91. The report shows that there was an entire absence of silver in the gold, a circumstance which we have never heard of before. It has always been the supposition that no gold was ever found without it contained a percentage of silver.

It will be seen that this gold was worth $20.51 per ounce, while absolutely pure gold is worth $20.67 per ounce. We believe that Rough and Ready can go on record as the producer of the purest gold dug from the ground. The mineral was taken out by Messrs. Hanley & Gross, who were partners at that time.

FEW realize how much good money the tramps cost this country. Accurate estimates of the number of these nomads are difficult to obtain. They are a variable quantity, but the number is formidable. In a lecture delivered in Boston recently by Prof. J. J. McCook, and reported in the Philadelphia *Ledger*, it was stated that there are about 46,000 male tramps wandering about in different parts of the country, eleven-twelfths of them being in the prime of life—that is, under fifty years of age. These men, the most of whom were able bodied, half of them having trades and nearly all of them able to read and write, cost the country, according to conservative opinion, from $8,000,000 to $10,000,000 annually. This is nearly half the cost of the navy.

The Prohibitive Seal Zone.

Written by PROF. GEO. DAVIDSON

On the 4th inst. the Geographical Society of the Pacific heard a paper read by Lieut. Commander F. J. Drake, U. S. N., commanding U. S. steamer Albatross, on "Recent Developments in Bering Sea." The lecturer stated, from his own observations, several facts about the fur seal, showing that the prohibitive zone of sixty miles radius, round the rookeries, is useless to protect the female seals in the breeding season. Outside of this connected double circle around St. Paul and St. George islands the decision of the Arbitration Commission permits the taking of seals by arrow and spear in a partial annular or zone about sixty miles wide extending from the east round by the south to the west northwest. The wonder has been why this outer partial zone was accepted by the contestants, but from Capt. Drake's developments we can readily conjecture. He has found that a branch of the Kuro Siwa, a warm stream of Japan, pushes across the middle of the Aleutian chain toward the Pribolof islands, St. Paul and St. George, through the two-thousand-fathom "deep," and carries with it the food fishes of the Aleutian islands. When this warm water, with a temperature of 42° Fahr., reaches the abrupt 100-fathom plateau of the Pribolof group it is met by the cold waters from the northeast part of Bering sea, which are mostly from the great rivers and is underrun by them. At the point of conflict the fishes of the warmer waters will not enter the cold-water area. There is a general absence of warm-water food fishes around the Pribolofs, and the female seals leaving their stations go to sea for food. They pass through the cold-water areas at a rate of twenty miles an hour and enter the warmer waters for food. Here the contents of their stomachs show the pelagic fishes that have come up from the Aleutians. This outer partial zone on the northern edge of the two-thousand-fathom deep is therefore their feeding ground during the season for supporting and feeding their young.

Now, it is a matter that can be sustained by proof that the Canadian pelagic fishers knew of this feeding ground, although they did not know the causes for the food supply. The Canadian Commissioners learned this, and communicated it to the authorities on their side, who kept very reticent in the matter, and made their terms of arbitration accordingly. The American Commissioners knew nothing of those very important facts and swallowed the pretty hook of holding sacred the inner sixty-mile zones, where relatively no seal food is found. As usual in arbitration, we got the string and the Canadians the pudding.

Last year the sealers reported 30,000 seals taken, nearly all females. For each female destroyed one young one died on the islands, and one embryonic seal was killed. Thus Capt. Drake estimates that 66,000 seals were destroyed last season. He has reported that at this rate of pelagic sealing it is but a few years when the whole herd will be reduced to a very few unless some cessation for one or more seasons be granted by the Governments. At present not only is the destruction great by the means allowed, but it is certain that some vessels use firearms, in which case they do not get more than one seal of every five that are shot, and it is within a reasonable estimate that last year's sealing cost the herd 100,000 seals, of which two-thirds were probably females.

Arizona Prospectors.

Arizona has few of the old-time prospectors left. Those who used to tramp over the hills with their burros in front of them have, like the antelope and buffalo, vanished and gone from sight. The prospector of to-day rides a bicycle forty miles and back, sleeps between sheets and takes a bath before going to bed.

Where an old timer would have spent six weeks in digging and picking from hill to hill, now a half an hour's gaze toward the horizon will convince the average prospector that some fellow has taken up the whole country, and he returns home, puts on his dressing gown and lighting his Havana, tells his wife that he has been prospecting and that there is "nothing in the new district which has not been taken up." The next day some more energetic person comes in with some rich rock, and the stampede is repeated over again.

What Arizona most needs at the preseut time is indefatigible prospectors who do not go crazy over a speck of gold, and who do not prospect with field glasses.—Prospector.

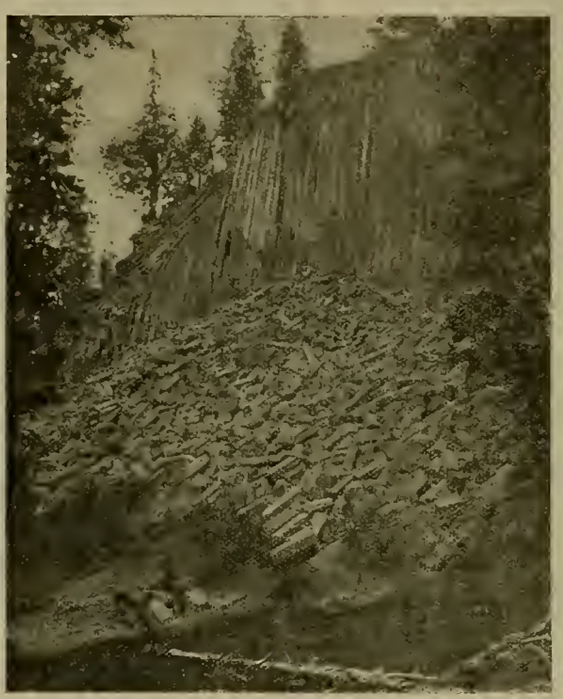
THE distance which derelicts traverse is much greater than is generally supposed. A careful record of observations has resulted in the preparation of a chart which shows that the hulk of the schooner Fannie E. Wolston has drifted, during the last five years, more than 10,000 miles. This calculation is based on forty-six reports of its having been sighted. Another derelict, which began its wanderings in 1891, drifted about 3500 miles up to the time it was last seen, when it had been afloat 615 days.

Red Rock, Goler and Summit Mining Districts in Kern County.

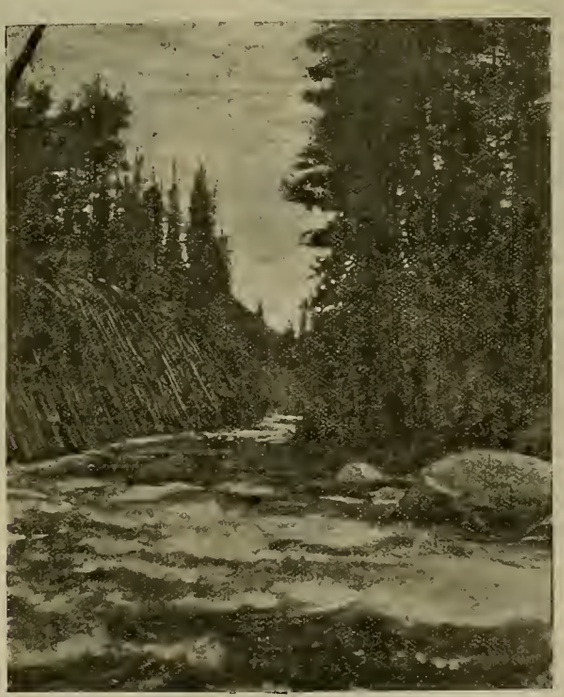
(Concluded from page 241.)

the gold is found on a sandstone bedrock, and in others in different layers in the gravels. Claims have been located for several miles, but owing to the scarcity of water but little is being done.

The Goler camps are situated at a depression of the range where a big canyon cuts through it, draining the sedimentary formations farther north. The Benson and Reed gulches, which were first discovered and in which big nuggets have been found, empty into the big canyon at its junction with the desert plains. These gulches are filled with volcanic and other bowlders, but do not head across the range. In Reed gulch a $1000 nugget was found. Just north of these rich gulches there are others much deeper and which empty into the big canyon. In these the bedrock outcrops in places; in others on the very irregular surface of the bedrock there is a thickness of nearly 100 feet of a cemented bowlder conglomerate, many of the granite bowlders being four to six feet in diameter. In the latter gulches the pay is also fairly good. The gold appears to be present as a concentration from the conglomerate.



COLUMNAR BASALT, NEAR HEAD OF KERN RIVER, CAL.



BASALTIC COLUMNS ON KERN RIVER, CAL.

At the Upper Goler camp, two miles above the lower, mining is also carried on along the slope of the mountains on which the sedimentary formations rest. Many shafts have been sunk in Benson gulch and in the others adjoining. In the former gulch the gold is the coarsest, there being many $10 to $50 nuggets. No quartz veins are found in the porphyry and slate in the vicinity of these gulches, and the source of the gold is quite problematical. The presence of the gold distributed sparingly in the conglomerates and more abundant in the gulches cutting them would indicate its derivation from the conglomerate. Strong currents must have been necessary to transport the huge granite bowlders so abundant at this point, but there are no definite traces of a river channel.

Summit camp lies eight miles east of Goler. At the former point the sandstone caps the ridge (the eastern prolongation of the El Paso range) and is in turn nearly hidden by the more recent wash. The shallow gulches which head in this ridge generally carry gold, though not always in workable quantities. It is said that prospects of gold can be found over much of the surface. This is the highest of the camps, having an elevation of 3300 feet. Water has to be hauled many miles. Although hundreds of claims have been located, only a few are being worked, and those not always successfully.

The same formation appears in places for some miles east of the Summit camp, but not much gold has been found.

Dry washers are used exclusively in these districts, but there are comparatively few places where the gold is abundant enough to make that method pay. If water can be introduced, there is without doubt a great future for the districts.

Fares and Prices at Cariboo.

A newly arrived Nevada county miner writes from Quesnelle Fork, Cariboo, B. C., under date of March 29, '95, to the Grass Valley *Telegraph* as follows:

From Grass Valley to Vancouver City, B. C., first-class fare with board included, is $30; from Vancouver to Ashcroft, our nearest railroad station, is $10.50; the stage fare from Ashcroft to here, a distance of over 200 miles, is $28.50, and their schedule time for the trip is four days, which an intending traveler must allow at the rate of $2 per day for living necessities. Many of the miners already here have walked the entire distance from Vancouver (over 400 miles) and claim they made $4 per day by so doing. Another thing I wish to state about this stage ride is that the small stations being more than thirty miles apart, yet their road far surpasses anything in the line of roads I ever beheld in Nevada county.

This mine is located on the south fork of the Quesnelle river, and is under the superintendency of J. B. Hobson, formerly of Placer county. At present the bank of gravel is 300 feet high, and as they follow it into the hill, it will become deeper. They have a line of twenty-two-inch pipe and one of eighteen-inch leading into the mine, with a pressure of 296 feet. These pipe lines feed two monitors of the Hoskins patent, using seven-inch nozzles. Their flumes are six feet wide and have ten-inch drop in twelve feet. Taking it all through, it is a well-equipped hydraulic mine, and, under the able management of Mr. Hobson, supported by T. D. Deasy, his foreman, formerly of Columbia Hill, Nevada county, should give big results to the shareholders in the near future.

I will quote prices on a few of the miners' supplies: Crack-proof gum boots, $10 per pair; flour, $8 to $10 per cwt.; pork, 25 cents per pound; rice, $15 per sack; eggs, $1.25 per dozen, and none at that; chickens, $3 each.

The wages here do not exceed those paid in Nevada county, and I would advise any one to stay in Nevada county unless assured of a job before starting, as there are three men here now for every job.

THE war between Japan and China was expected to show what the world might look for from the first-class war ships and guns which all nations have lately been arming themselves with. It was expected that one side or the other would very quickly collapse under the terrific fire which each could pour into the other. It was the Chinese war vessels that gave in almost at the beginning. But on land the Chinese showed the same inability to make a desperate fight under fire. So the authorities are as much at a loss as ever. It is not ships and guns that have been tested, but men. It is, indeed, "the man behind the gun" to whom the praise for success is due. In all the wars in which this country has been engaged American superiority has been plainly manifested, and this has been true on the sea, when American vessels were pitted against British ships.

The Silver Problem.

To the Editor:—There seems to be so much confusion in the minds of people generally in regard to what "free coinage of silver" means and also about the aims to attain it, that a brief outline of it might be given here to advantage: In the first place, if we had an ample volume of money in the world there would be no need of any further silver coinage; and this being the case, the decision of the question as to how much money we really need seems to be the hinging point. Then, unless we consent that the earnings of money loaned should be greater than those of productive industries of all kinds, we must finally determine that unless we secure such a volume of money as would, by its plenitude, cheapen money and increase the price of everything else that is now so much lower than the money-lender's profits, the rates of profit for lending money must continue to remain so disproportionately high as to perpetuate our dull times. To illustrate: For the thirty years between 1860 and 1890 the increase of wealth in this country, as an entirety, was only about 2½% per cent per annum; in other words, money lenders and everybody else were only entitled to 2½% per annum increase or interest on their investments for that time. If any industry or interest got more than that it received more than an equitable share, and the other industries and interests had to be impoverished as a consequence in the degree that one or more got over 2½%.

Interest on money in California averages over 8% per annum, as shown by the census reports. It is no doubt cheaper in some Eastern States. Accepting 8% as the basis of estimate for money's interest and 2½% as the increase of wealth in the whole country, we find under the law of proportion that with $24 per capita as the present amount of circulating medium in this country, we need at least $96 per capita in the United States to bring the earnings of money down to the earnings of other things, or four times the volume of money we now have.

Hence "free coinage of silver" means more money, and the great struggle to attain it means the people's great desire to throw off financial bondage. The following are some of the results that would be accomplished by free coinage:

Many millions of people would, directly and indirectly, be put on a living basis at once in the production, reduction, transportation, etc., of the metal.

The increase in the volume of money it would give to the world, with the advanced price it would place upon commodities, would enhance the share of the wealth falling to the industrial element of our population by many billions of dollars.

It would double the present price of wheat, cotton and all the other staple products of this country, and at the same time double the price of the land upon which they are raised, as was the case in the early '50s when so much gold was being produced.

It would restore the original value to those who invested, under the sanction of law, in about one billion dollars' worth of mining property. These were vested rights and were confiscated by law, by the demonetization of silver.

If other former bi-metallic countries refused to adopt free coinage, our doing so would give us practically all of the trade of the 700,000,000 people using the single silver standard.

There is only four billion dollars of silver money on the globe, with 4000 years of production. If all of it were in the United States and if it were all coined into our money, it would give our population less than $60 per capita, or only about two-thirds of the amount we need right now. Hence, as we could absorb it all and still have only two-thirds of enough (granting that we would have no other money), we can certainly, as a nation, undertake free coinage alone, without the consent or assistance of any other country or Government on earth. And that is what our Government should do, and do it immediately.

No sane-minded person will attempt to say that if our Government made silver money full legal tender in all amounts, the public generally would refuse to accept it. The law would not only force them to do so in that case, but they would gladly do so. Further, the whole world would be glad to accept it, for the reason that they could buy our products with it in that case. The outside world will always honor any of our money that we will ourselves honor, for the reason that they can buy with it anything we have to sell.

The wicked statements that we cannot resume free coinage without any international agreement whatever are a mixture of cowardice, ignorance and falsehoods. Many men, knowing better, make the statement for the purpose of misleading.

With gold and silver combined (if no other kind were used) there is not one-tenth of enough money in the world to give a just and equitable distribution of the wealth of the world to those who produce it.

The bankers' congress sitting in the national capitol at Washington, misrepresenting the people, tells us that if we had free coinage all the gold would leave the country. Our eighty years of free coinage previous to 1873 showed that our ratio of 16 to 1 drove all the silver to foreign countries, and brought us their gold. The reason was that Europe's ratio is 15½ to 1 and India's and China's is 15 to 1, so that our ratio being more in favor of gold than theirs, which means that we offered more for gold than they did and that they offered more for silver than we did, by the respective ratios, the two metals each went to their highest markets.

Gold and silver are twin sisters, rocked in the same rock-ribbed cradle by Nature. What God hath joined together let no man put asunder! Gold is never found in quartz without the presence of silver, but silver is sometimes found without the presence of gold.

Gold and silver would not be mined at all simply as commodities, as the shutting down of the silver mines of the country to-day practically illustrates; and there is not a single one being opened at the present time. Their money uses give gold and silver at least three-fourths of their market price. It has cost at least $1.50 to produce each dollar's worth of gold and silver in the world to-day.

I would say to those who are afraid that if we had free coinage the balance of the world would not accept our money without an international bi-metallic agreement, that they should consider the case of our greenback which goes all over Europe at a premium to-day, simply because it can be returned to the United States cheaper than coin, and it will buy as big a dollar's worth of wheat and pork as a gold dollar will. Now, if our paper dollar with no intrinsic value whatever will pass in foreign lands at a premium, why should not silver, bearing the same stamp and fiat as our paper dollar, pass at least at par?

Remember, there is no such thing as "international" money and from the nature of things there never can be, as the creation of money is always the expression of the supreme function of any Government. But unless a Government in exercising that function endows its own circulating medium with all the powers and qualities of full legal tender, for both public and private debts, it cannot expect other nations to honor that medium, for they will not do so.

One so often hears it stated that none but silver miners would be benefited by free coinage. Let us see if that statement is true, after considering the subjoined very conservative estimate of losses occasioned to our several industries by having half the metallic money of the world destroyed, as was the case when silver was demonetized. The figures are paralyzing in their magnitude, but are under rather than over stated:

LOSSES IN THE PAST TWENTY YEARS THROUGH THE DEMONETIZATION OF SILVER.

Shrinkage in real estate values	$10,000,000,000
Labor of one million (aver.) idle men at $2 a day.	15,000,000,000
Depreciation of silver miners' bullion	250,000,000
Cotton planters' product	3,500,000,000
Wheat farmers' product	7,000,000,000
Corn, oats, etc., farmers' product	7,000,000,000
Cattle, sheep and horse raisers' product	7,000,000,000
Increase of mortgage indebtedness by decreasing ability of debtors to pay, because of scarcer volume of money	10,000,000,000
Excessive interest paid because of restricted volume of money and consequent usury	10,000,000,000
Shrinkage of values in iron industry	5,250,000,000
" " lumber, lime, etc	5,000,000,000
" " all descriptions of manufacturing	10,000,000,000
" " copper, lead, zinc, coal and various sundries (low estimate)	5,000,000,000
Total	$95,000,000,000

It will be noted that the silver miners' proportion of the above loss is only one-three hundred and fortieth, while their proportion of the total investment of the country is only one-sixtieth. The silver miners, therefore, lose only about one-sixth as great a proportion as the agriculturists and other industries. Who, then, in the name of common sense will, in the face of such a marvelous array of facts, contend that the general industries of the country are not interested in again establishing free coinage of silver at the ratio of 16 to 1?

In reading over the above table it will be remembered that the losses shown are much larger than the total valuation of all wealth in the United States to-day. But in this connection it must also be borne in mind that if silver had never been demonetized our total national wealth would be perhaps twice its present amount, by the extra opportunities and stimulus that silver would have given to production and enterprise. Green Majors.

Alameda, Cal., April 16th, '95.

Shasta County Mining Notes.

To the Editor:—When the Iron Mountain changed hands, everybody was hopeful and expected a genuine stir, but it has failed to materialize. The first religious rite the English owners performed was to cut the wages of the old employes and offer the newcomers one dollar per day for underground work. They now have about eighty-five or ninety men employed, about one-third of whom are employed surveying and locating mining claims so as to cut the timber for fuel. Report has it that they are experimenting in the east with the cyanide process and intend to try it before attempting to smelt.

French Gulch has a small mine owned by Ellery Brothers that is producing phenomenally rich ore; thirty tons yielded $2700.

Since the new management took charge of the Gladstone, it is making between $6000 and $7000 net per month. The engineer of the mill, who was arrested with a bar of stolen bullion in his possession, slipped through the meshes of the law by claiming that Mr. Gray, the superintendent, gave it to him for wages. An indictment for Gray for stealing bullion was found by the grand jury, but Mr. Gray was last heard from in Panama on his way to South America.

The old Washington mine in French Gulch is under bond to a New York party.

The Niagara is worked on the tribute system and yields fair results.

Around Shasta and Middle Creek a great many prospects are being worked with the usual results. The mines are bunchy on Flat creek and Spring creek. The same results are obtained at Squaw creek. The Uncle Sam makes as fine a record as the county can boast of. They pay their men and the mine yields handsomely. The Windy Camp mines are still in the same stage of development that they were twelve years ago—just going to do something, but do not get there. In the Old Diggings, Hart's Texas and Georgia runs steadily. They have a big strike periodically once a week the year round, but the mortgages on the property still remain on record, which do not corroborate the statements of the owners.

The Quartz Hill property had a shut-down and general squabble among the stockholders, with the result that the manager was discharged, the trouble being the mine did not pay. They have started up again under the management of the president.

The base range of Shasta county extends for a distance of thirty miles. It commences at Iron Mountain and runs northeast and then swings south to Furnaceville, or the old Afterthought mine.

The best dividend-payer in the county for the investment is the dredge working in the river. It cost about $3000 and earned $5000 net for the owners last summer. This year they have doubled its capacity and will double the yield. They dredge out boulders weighing over a ton and get the best pay in the boulder ground. Two other dredges are being constructed by other parties, and river dredging has become a factor in mining in this section. F.

Books Received.

"*Motive Powers and Their Practical Selection*" is a new work on an old subject by Reginald Bolton, who dedicates it to the Institution of Civil Engineers of England and the American Society of Civil Engineers. Every application of power: manual and animal; wind and water; steam and gas; hot air and electricity, receive practical comment, the book being a clever compilation of facts gathered from a variety of authentic sources. Valuable tables, formulæ, etc., are presented and in all cases the cost of the means of power under discussion is given.

Argument or opinion has little place, the author almost entirely confining himself to statements of fact, and an honest effort is evident to be fair and unprejudiced in all his assertions, and its practical nature makes the work of value to any man having anything to do with the subject of which it treats. It contains 252 pages, octavo, and is handsomely issued by Messrs. Longmans, Green & Co., 39 Paternoster Row, E. C., London, England, and 15 East 16th St., New York City.

"*Elements of Mineralogy, Crystallography and Blowpipe Analysis, from a Practical Standpoint*, including a description of all useful minerals, the tests necessary for their identification, the recognition and measurement of their crystals, and a concise statement of their uses in the arts," by Alfred J. Moses, E. M., Ph. D., and Chas. Lathrop Parsons, B. S., is received from the publishing house of D. Van Nostrand Co., 23 Murray St., New York City.

In this book of 342 pages, inorganic nature receives plain and practical exposition. Part I is devoted to a description of the crystalline structure of minerals, their form and the laws that govern its construction; part II is a treatise on blowpipe analysis; part III (probably the most interesting to the general student) is devoted entirely to descriptive mineralogy: simple, accurate and concise; part IV treats of determinative mineralogy, giving several valuable test tables, by use of which the presence or absence of the principal minerals can be determined. The book is of value to the practical miner or metallurgist. It contains over 300 figures or delineations of mineral crystallization and is so arranged as to readily yield the information desired.

Sierra Buttes Mining Company.

The accounts of the Sierra Buttes Mine for the half-year ended December 31st last show, including £2964, the moiety of profit from the Uncle Sam Mine, a balance to the credit of profit and loss of £3608. Out of this the directors recommend a dividend of 6d. per share, free of income-tax, £3062, a balance of £546 being carried forward. The accounts of the Plumas Eureka Mine for the half-year show a profit for that period of £4759, inclusive of £2964, the moiety of profit from the Uncle Sam Mine; this, with the balance brought forward, enables the directors to recommend that a dividend of 9d. per share, free of income tax, be declared, and that £4802 be carried forward.—Loudon Mining Journal, March 23.

The American Institute of Mining Engineers are on their annual excursion this time to Florida, leaving Washington, 125 strong, under charge of Dr. David T. Day, of the geological survey.

The Crawford Mill.

Herewith is presented a sectional cut of the Crawford Gold Extractor, a mill for which many advantages are claimed by its makers, who say that "from actual experience of this mill, and from the most careful study of its operation, it may be pronounced almost perfect as a gold saver."

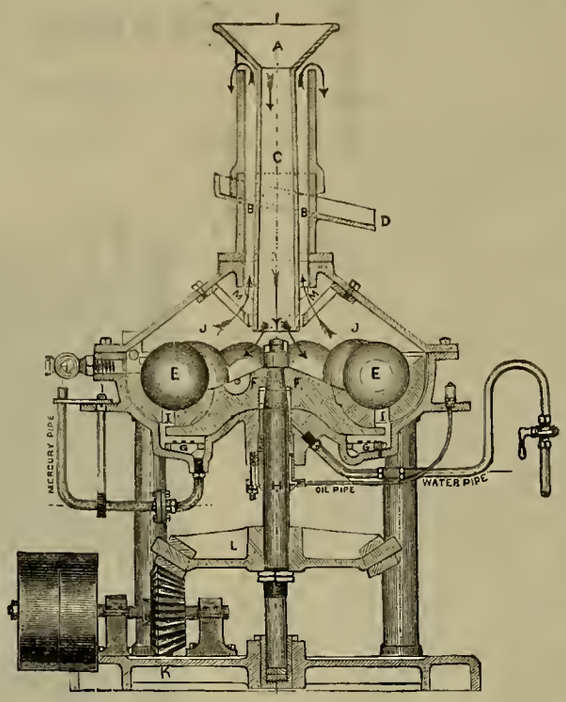
The ore is fed into the conical-shaped hopper *A*, passes downward in the direction of the arrows through the tube *C*, and falls upon the rotary disc *F F*, which throws the ore with force under the balls *E E*, where it is ground to an almost impalpable powder (from 100 to 200 mesh), the gold particles alone, owing to their specific gravity, falling through the space *I I* into the mercury bath, *G G*.

Rapid motion is imparted to the balls by the disc *F F*, which makes about eighty revolutions per minute. The water entering through the water pipe passes under the rotary disc *F F*, and flows over the mercury *G G*, then upward through the opening *I I*, and, filling the space *J J*, carries upward the tailings in the direction of the arrows, through the neck *B B*, and flows out over the top, the tailings going to waste at *D*.

The rotary motion of the water in the mill is checked by the flanges *M M*, and also by flanges on the neck of the hopper, *B B*. By this means the violent agitation of the water ceases before it overflows the top, and thus the fine particles of light gold are not borne away but settle back into the mill and eventually reach the mercury. *H* is the vertical shaft which gives motion to the disc *F F*. Motion is imparted to the shaft *H* by a bevel gear *K* and *L*.

The mill is constructed on the arrastra "pan-type" principle, the ore crushing being effected by steel balls set rotatively on two half-circle annular grooves, the inner one being the periphery of a convex disc, running at a speed of about eighty revolutions per minute, the outer a fixed ring. A space between these two "seat grooves" of one-half inch forms the entrance to an annular trough containing quicksilver and placed at the bottom of the pan below the ball seat.

The transmitted power being below the pan, the ore, broken to the size of not more than one-half-inch mesh, is fed in through a hopper head, falls on the pan about twelve inches and comes in coutact with the crushing balls. A steady stream of water under pressure enters the mill from below, plays over the quicksilver, and then flows upward into the body of the mill. The ore is held in suspension until it is ground into impalpable powder by the balls, the gold particles alone, by their specific gravity, dropping down into the naked quicksilver. The tailings as residue, instead of leaving the mill at the point below the crushing level, through screens or amalgam plates, as in stamp or other crushing systems, has to rise with the water through a grating and flow off at the feed elevation. Notwithstanding its simplicity, the mill combines in itself a grinder, pulverizer, amalgamator, settler and cleaner-up.



SECTIONAL VIEW OF THE CRAWFORD MILL.

It requires 12 H. P. and about four gallons of water per minute. This mill was introduced upon the market some three years ago. It is claimed but a single fault has been found with it, and that, its excessive wear and tear on some ores. This defect, however, the manufacturers say has been overcome, a special steel having been finally adopted, by the use of which the wear and tear is reduced to a maximum of thirty cents per ton of ore treated. The foundation for the mill is inexpensive and can easily be constructed in a day.

The mill, in its present form, is not advocated for use on ores carrying more than fifteen to twenty per cent of sulphurets, as an increased percentage reduces proportionately the capacity of the mill. Its average capacity is ten tons.

There is but little, if any, loss of quick, and millmen will appreciate one unique feature, namely, the amalgam is accessible only when the mill is partially dismantled to effect the periodical cleanup.

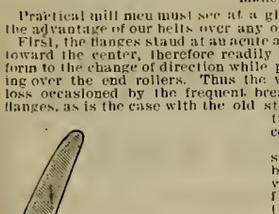
Several mills have recently been sold to companies in Baker City and Huntington, Oregon, and Wallace and Kendrick, Idaho. At the Northwest Development & Investment Company's mine, in Wallace, a trial run recently with one of these mills, during eight and a half days, yielded a cleanup of 98½ ounces, or a saving of nearly ninety per cent. Three mills in operation for the last three years at Kane Springs, Utah, report a saving of over eighty-five per cent on refractory ore.

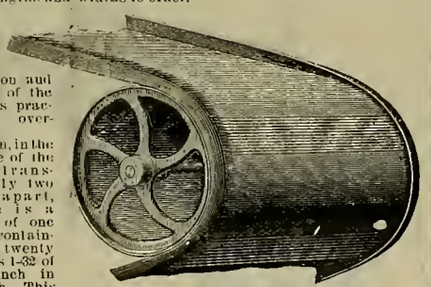
The mill is controlled and manufactured by the Mechanical Gold Extractor Company, 47 Broadway, New York City; W. O. Ross, secretary.

THE annual meeting of the American Association for the Advancement of Science will be held in this city during the second week of next August.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.



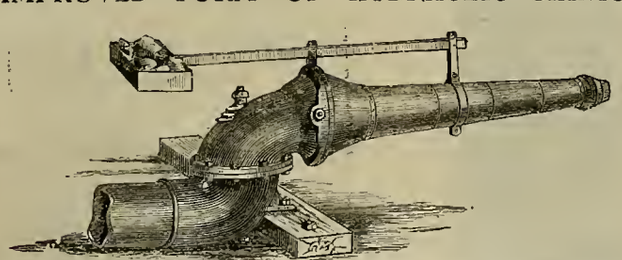


Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome. Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

H. G. BLASDEL, JR., Manager,

419 California Street, Haywards Building ..... San Francisco.

IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

PLACER Amalgamators, : Dredgers, : Shovels.

Complete "Lancaster" Gravity Gold Amalgamating, Hoisting and Dredging plants furnished for treating large quantities of low grade placer ground and pulverized free milling quartz at small cost with minimum supply of water. **Highest possible Gold yield insured.**

The "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways are of the most improved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required. **Crushing, Pulverizing, Concentrating, Screening, Pile Driving and other machinery also built.** Investigation and correspondence solicited.

JAMES H. LANCASTER, Patentee, 39 Cortlandt St., NEW YORK.

Scientific Progress.

Terrestrial Helium.

Lord Rayleigh, the first to isolate from the air the gas argon, whose existence was never known until last year, is now said to have made another very interesting discovery. Chemical analysis of the substances composing the earth's crust has thus far revealed nearly seventy distinct elements; and spectroscopic study of the sun has already detected the presence of more than half of them in that body. But there are indications that the sun contains a few elements which are yet unrecognized in terrestrial matter. For instance, there is a line in the green part of the spectrum of the outermost solar envelope, the corona, which is thought to represent a gas much lighter than hydrogen. The line itself is numbered 1,474 in the old Kirchhoff scale, but in Rowland's, which is the modern standard, it is set down at 5,316. The substance itself is called "coronium." Nothing of the sort has been found on the earth. Again, when the spectroscopists examine the chromosphere, the layer of gas next below the corona, but lying above the luminous cloud-shell of the sun, they discover in the yellow a brilliant line, which they used to call "D3," but which is situated at 5,876 in Rowland's scale. No line could be perceived at this point in the spectrum of any terrestrial substance, and hence the element thus signified was, like coronium, regarded as peculiar to the sun. Indeed, such a supposition is embodied in its name, "helium." Since the first discovery of the D3 line, however, the latter has been recognized in the spectra of a few stars, which are also suns, but many million times as far away from us as our own. And now comes the report that Lord Rayleigh has just found helium in a rare mineral from Norway.

This famous chemist was testing a rock specimen, with sulphuric acid. Such tests of that particular mineral have been made before, and they always yielded a gas. Heretofore the latter has been believed to be nitrogen merely. But Lord Rayleigh perceived that it was argon; and, what is more, that some other gas was combined with it. As this sort of experience is precisely what led him to make his brilliant discovery of last year, one can readily understand the zeal with which he sought to ascertain the nature of the adulterating gas. His further investigation led him to identify it with helium! Another eminent expert, Professor Crookes, has confirmed this conclusion.

From the particular region in the sun in which helium is found, and from its immediate and intimate associations, this gas is looked upon as being one of the lightest materials composing the body, possibly as light as hydrogen. Wilsing, a leading German astronomical spectroscopist, is inclined to think that helium resides chiefly in the upper part of the chromospheric sheet, which would suggest the idea that, like coronium, it may weigh even less than the gas in whose company it has usually been hitherto. Some researches of Gruenewald, in which Professor Young placed confidence, indicated that possibly helium and coronium were components of hydrogen, and were partially dissociated by intense heat; but this theory seems to be effectually disposed of by Lord Rayleigh's ability to obtain the gas at very ordinary temperatures, and in combination with argon.

One of the principles on which stars are classified is that of resemblance and difference between their spectra. And in such classification various attempts have been made to indicate the stage of advancement attained by each particular orb in its life history. Dr. Scheiner, whose book on stellar spectroscopy is not only the latest but probably the ablest work of its kind extant, puts those stars whose spectra contain the bright lines of helium and hydrogen in the first sub-division of his first class, in point of evolution. Beta Lyræ and Gamma Cassiopeiæ are two such stars. He fancies that they have atmospheres composed of those gases, enormously extensive as compared with those of other stars, and possibly hotter than the gaseous envelopes of their older companions. In view of these theories one cannot but ask how long it is since our world was in the condition of Beta Lyræ, whether any helium now floats in our outer atmosphere, how that particular portion which is now imbedded in the earth's crust got there, and other similar questions.

A New Blasting Powder.

Several of the explosives used in blasting within the last few years have been combinations in which chlorate of potash forms a conspicuous element. With petroleum it makes "rack-a-rock;" with saltpeter and crude gamboge the "oriental powder," once used in opening oil wells in Pennsylvania, and with potassium-ferro, ferri-cyanide and sugar an article known both as "white gunpowder" and "German gunpowder." This same salt has also been mixed with sulphur and various other materials for the same general purpose. A new compound of the chlorate, with sugar only, is now reported from South Africa. It is called "thorite," probably after the Scandinavian god of thunder, Thor. For several months this explosive has been tested in coal mines at Vereeniging and elsewhere, with excellent results. It is said to be almost as powerful as dynamite, weight for weight, cheaper to make, and virtually free from unpleasant fumes. Sir Frederick Abel, one of the inventors of cordite and a leading authority on explosives in England, has sent an expert to Capetown to establish a laboratory for further experiments. Wherein the superiority of thorite over other potassium chlorate powders lies is not indicated in the brief press notices of it at hand. In some of the mixtures used, especially those containing resinous gums, the particles become consolidated by heat, a result impairing the efficiency of the product, and one which it would not be safe to overcome by trituration. One would anticipate that moisture would affect sugar in a similar way. But possibly thorite is guarded from damp air scrupulously until it is used.

THE greatest height of any cloud yet measured is 43,800 feet, and the highest velocity is 112 miles an hour for a cloud at 28,000 feet. The most important result thus far reached from these measurements is the fact that clouds are quite regularly distributed in three layers, the mean summer levels for Upsala being: low clouds—stratus, cumulos, cumulo-nimbus: two thousand to six thousand feet; middle clouds—strato-cirrus, cumulo-cirrus: twelve thousand to fifteen thousand feet; high clouds—cirrus, cirro-stratus, cirro-cumulus, twenty thousand to twenty-seven thousand feet.

Mechanical Progress.

How an Ax is Made.

On entering the main workshop the first step in the operation which is seen is the formation of the ax head without the blade. The glowing flat iron bars are withdrawn from the furnace and are taken to a powerful and somewhat complicated machine, which performs upon them four distinct operations, shaping the metal to form the upper and lower parts of the ax, then the eye, and finally doubling the piece over so that the whole can be welded together. Next, the iron is put in a powerful natural-gas furnace and heated to a white heat. Taken out, it goes under a tilt hammer and is welded in a second. This done, one blow from the "drop" and the poll of the ax is completed and firmly welded. Two crews of men are doing this class of work, and each crew can make 1500 axes per day.

When the ax leaves the drop, there is some superfluous metal still adhering to the edges and forming what is technically known as a "fin." To get rid of the fin, the ax is again heated in a furnace and then taken in hand by a sawyer, who trims the ends and edges. The operator has a glass in front of him to protect his eyes from the sparks which fly off by hundreds as the hot metal is pressed against the rapidly revolving saw. The iron part of the ax is now complete. The steel for the blade, after being heated, is cut by machinery and shaped. It is then ready for the welding department. A groove is cut into the edge of the iron, the steel of the blade inserted, and the whole firmly welded by machine hammers. Next comes the operation of tempering. The steel portion of the ax is heated by being inserted in pots of molten lead, the blade only being immersed. It is then cooled by dipping in water, and goes to the hands of the inspector. An ax is subject to rigid tests before it is pronounced perfect. The steel must be of the required temper, the weight of all axes of the same size must be uniform, all must be ground alike, and in various other ways conform to an established standard. The inspector who tests the quality of steel does so by hammering the blade and striking the edge to ascertain whether it be too brittle or not. An ax that breaks during the test is thrown aside to be made over.

Before the material of the ax is in the proper shape, it has been heated five times, including the tempering process, and the ax, when completed, has passed through the hands of about forty workmen, each of whom has done something toward perfecting it. After passing inspection, the axes go to the grinding department, and from that to the polishers, who finish them upon emery wheels.—Blacksmith and Wheelwright.

Rating of Feed Water Heaters.

The Feed Water Heater Manufacturers' Association, composed of seven companies manufacturing closed feed-water heaters, has issued a circular in which the resolutions recently adopted are printed. The resolutions set forth the belief of the association that the only proper rating for feed-water heaters is based on the square feet of heating space on the heater, that they agree to specify the square feet in each heater on which a price is quoted, and that they will "in each and every case state without reservation, both in printed catalogues and in specifications, the diameter of the tubes, the number of lineal feet thereof and the total square feet of heating surface in each heater offered."

It also says that "the term H. P., as applied to feed-water heaters, is an exceedingly loose and indefinite phrase. The work which a feed-water heater has to do depends upon the number of pounds of water in the shape of steam that an engine requires per hour."

The following is also printed in the circular: "A simple engine, of the cheapest grade, may use say fifty pounds of water per H. P. per hour; an average engine will use perhaps thirty pounds of water, while a high-grade engine will cut the consumption of water down to something like fifteen pounds per H. P. per hour. Again, the steam which is used to heat this water will, in the case of a simple engine, have a temperature of 212°, while in the engines of high grade it may have to do its work with a temperature of less than 150°."

The subject was recently discussed in the American Society of Mechanical Engineers.

Some Comparisons Bearing Upon Engineering Construction.

Some comparisons of an important practical character, in their bearing upon engineering construction, have recently been made by Professor Thurston. From these it appears that cast iron weighs 444 pounds to the cubic foot, and an inch-square bar will sustain a weight of 16,500 pounds; bronze, weight 525 pounds, with a tenacity of 36,000; wrought iron, weight 480 pounds, with a tenacity of 50,000; hard "struck" steel, weight 490 pounds, with a tenacity of 78,000; aluminum, weight 168 pounds, with a tenacity of 26,000. Singularly enough, if equal weights of metals and wood be compared, it is found that several varieties of wood are stouter than ordinary steel. Thus a bar of pipe just as heavy as, but no heavier than, a bar of steel an inch square will hold up 125,000 pounds, the best ash 175,000, and some hemlock 200,000, but the bulkiness of wood is a great objection. The tenacity of the best steel castings made for the United States navy is given as from 65,000 to 75,000 pounds to the square inch. By solidifying such castings under great pressure, double that tensile strength has been reached.

Not Following Instructions.

In criticising the lax methods used by certain people in handling tools or new devices, a writer in the *Plumbers' Trade Journal* says that manufacturers are afraid to send out anything new, scientific or novel, for they know into what hands it is apt to fall. All new stuff should bear a tag inscribed as follows: "Do just the opposite to what you think is right, and this fixture will work perfectly." In the good old days, it took five years to learn plumbing, but now an intelligent man could, in five days, learn more than a great many who command first-class wages know. In days gone by, plumbers were never known to say a thing was complicated. They were glad to have ideas that were puzzling. To be able to make repairs on over two hundred different kinds of valves was their stock in trade, and a lack of this knowledge barred out pauper competition. To-day if a tramp is unable to get an article to work, it is condemned, and the trade is reduced simply to delivering the materials on the ground and distributing them to their various positions, the same as chairs or bedsteads.

Bridges of Old Rails.

New economies suggest themselves quickly in these days, and one of the latest to crop up on the surface is the construction of railway bridges out of old rail. The Baltimore & Ohio road has two of these structures built out of scrap such as accumulates in the stock of any line. The old rails were valued at $9.50 a ton. The angles from which the hangers were made were of short lengths that were spliced at their centers. All gusset plates were cut out of old web plates which had been punched for other purposes. The two bridges were constructed in the repair shops of the company and required but the simplest tools in their manufacture. The advantage of this curious innovation is that the old rails, which are always on hand, can be utilized, and the cash outlay is so small on the whole job that the total cost is brought well within the price at which the cheapest wooden bridges can safely be built.

Professional Cards.

A. H. RICKETTS, Attorney-at-Law,
Mining Patents and matters before the Land Department a Specialty.
Crocker Building, Rooms 201, 202 and 203, San Francisco.

The Evans Assay Office.
W. N. JEHU, - - - - Proprietor.
Successor to Jehu & Ogden.
628 Montgomery Street, San Francisco.
Rooms 46 and 47 Montgomery Block.
Ore Assays, Analyses of Minerals, Metals and their Alloys, Etc.
LESSONS GIVEN IN ASSAYING.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering.
Surveying, Architecture, Drawing and Assaying.
723 Market St., San Francisco, Cal.
OPEN ALL YEAR.
A. VAN DER NAILLEN, President.
Assaying of Ores, $5; Bullion and Chlorination Assay, $25; Blowpipe Assay, $10. Full Course of Assaying, $50. Established 1864.
☞ Send for Circular.

JOHN W. GRAY, Engineer and Surveyor.
Examination, Surveys, and Reports upon Mines, Drainage, Tunnels, etc.
Development of water for mining and domestic use, irrigation, and the production of power. General Surveying of all kinds, and plans prepared. Construction work superintended. Correspondence solicited.
Res.—923 Linden St., Oakland, Cal.

EDWARD S. COBB,
Mechanical Engineer and Expert.
Tests and Estimates for the improvement of Pumping, Power and Hydraulic Plants.
Will supervise the Construction, Shipment or Erection of Machinery. Will make Drawings, Estimates or Specifications.
Prices obtained for machinery of every description. Twenty year's experience.
23 Davis St., Rooms 30 & 31, S. F., Cal.

GILES OTIS PEARCE,
Mineralogist and Metallurgist.
708 Colorado Avenue, Colorado City, Colo.
Will examine Mines, Ore Bodies, Mineral Belts or Zones, and make written Mineraliet Reports, fees for which made known upon application for services. I make my own assays and select my own samples when examining mines. Eighteen years' experience. Analysis of water and soils.

CHAS. S. HARKER, E. M.,
Attorney-at-Law and Mining Engineer.
Makes a specialty of *Mining Law*. Patents obtained on mineral and agricultural lands. *Investments and reports made.*
Full charge taken of property for absent owners.
Offices: 16 & 17 No. 26 Montgomery St., SAN FRANCISCO, CAL.

Almarin B. Paul, M. E.,
Mining Operator,
ROOM 5, CROCKER BUILDING.
Cor. Market and Montgomery Sts., San Francisco.
Will give attention to the sale of and reporting on RELIABLE Mining Properties, or the procuring of suitable Machinery for interest in Developed Mines.
Plans and Estimates made for IMPROVED CYANIDE PROCESS PLANTS, and competent instruction for working the same on a large, practical scale.

Nevada Metallurgical Works,
No. 23 Stevenson Street,
Near First and Market Sts., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE ALPINE MINE.—*Republican:* The prospecting operations at the Alpine mine, in Plymouth, have led to the discovery of a three-foot vein of excellent rock. The strike promises much for Plymouth. The town has been in a depressed condition for seven or eight years—ever since the fire which put the quietus on the Plymouth Consolidated mine. Brief intervals of mining excitement have raised hopes of better times two or three times since, but have proven delusive. The cutting of a fair-sized ledge of pay ore, right in the town limits, gives more substantial hope of restoring the town to prosperity than anything that has taken place in that vicinity for years.

MISCELLANEOUS.—The five-stamp mill of the Smith Brothers on the Clough place, near Volcano, is still idle. It is probable that the idleness will not be of long continuance. It is reported that the ore in the test crushing yielded $4 per ton. With a mill of one battery of course it would not pay. It is doubtful if rock of that average could be made to pay with a 10-stamp mill. With 20 or 40 stamps, however, it ought to be made to pay a handsome profit. There is said to be a large body of ore, equal to keeping a fair-sized mill in active operation.

The Clinton Bar Company have been engaged in rearranging their machinery for the better working of their rich gravel claim on the Mokelumne river.

The sum of $1000 was paid by D. Gutmann, in behalf of the Alma Mining Company, to Rube and Jefferson Boxall last Friday, being the first installment on the bond for all the Boxall interest in the Alma ground. The price is $5000, and the time expired on the 5th of April. The company paid $1000 on the price, and secured an agreement extending the time for the balance of $4300 until the 5th of June. This payment is a guarantee that the purchase will be consummated.

Calaveras.

THE TABLE MOUNTAIN MINE.—It is expected that the new ten-stamp mill at the Table Mountain mine will be ready for operation by May 1st.

Mariposa.

MAKING PROGRESS.—*Gazette:* The Merced Mining Company is having a road built from the Malvina mine to Coulterville. At the Potosi mine preparations are being made to put in a compressor to run the Burleigh drills, and the Potosi and Malvina are both being connected with the main shaft by tunnels. The shaft at the Mary Harrison is being retimbered. Work on the ditch to convey water from the south fork of the Tuolumne river will soon be begun.

ACTIVE OPERATIONS RENEWED.—W. S. Chapman returned from Mariposa during the week. His company has the old Hite mine and will go ahead with work this summer. Everything in and around the mine is just as it was ten years ago when the air compressor broke. The first thing Mr. Chapman and his associates will do is to pump out the mine; then begin work on the 300-foot level. The Hite was a big producer and gives promise of even greater productiveness.

Mr. Chapman is also interested in the Vanderbilt, 13 miles from Mariposa, now known as the Sunset. The ten stamps now there are to have ten additional, and the twenty will pound this summer.

Nevada.

THE CEDAR MINE.—*Tidings:* The Cedar mine, about twelve miles below Grass Valley, is looking exceedingly well. This mine is in charge of Jas. R. Nickerson. There is now a twelve-foot ledge of quartz in the mine and assays from portions of it have gone above $60 per ton. The rock is uniformly good.

THE W. Y. O. D.—The W. Y. O. D. mine, which has one of the best plants of any mine in the district, or State, will soon have ten additional stamps to grind out the precious metal.

The company is now considering bids for the new improvement and there will be no delay in having the work done as soon as the contract is let. The Union learns from a reliable source that the mine has shown great improvement of late in the quality of the ore, which warrants going to the expense of increasing the capacity of the mill. In fact it may be said that dividends are again in sight.

The work of running the drift and sinking the shaft have been vigorously pushed and the mine is so well opened that the full force of men can be employed in stoping the quartz when the capacity of the mill will admit of crushing all the ore that may be extracted through it.

The principal work is now being done in the shaft and the 1300, 1200, 700, and 1000 levels.

Fifty men are employed at the W. Y. O. D., nearly all of whom are on day's pay.

THE GOLD RIDGE MINE.—*Tidings:* The Gold Ridge mine, in the northern part of the county, not far from North Bloomfield, is making arrangements to put up a forty-stamp mill. They have an immense ledge of quartz, and they are running a tunnel, which is in about 200 feet, for a gravel channel which is known to be rich. The mill site will be located in Sierra county. Richard Phelan is superintendent of the Gold Ridge.

THE NATIONAL.—The National mine, located one and a half miles from Graniteville, has begun operations after having been closed down during the winter on account of the ditch being blocked with snow. The National ordinarily employs twelve to fifteen men.

GOOD RETURNS.—*Tidings:* Three tons of quartz from the Morgan and Tilley ledge in Willow valley were recently shipped to San Francisco and treated by the Selby Smelting Works. It brought over $70 to the ton. The ore is rebellious and does not pay by the ordinary milling process.

A GOOD SHOWING.—The *Transcript* says the amount of money paid out for labor at the mines in that district during the past month was larger than has been paid out in one month for a similar purpose in many years before. It is also said that the number of men engaged in mining exceeds considerably what it has been for many years. "This improvement has been steady and substantial and the increase in the number of men employed has been gradual and is likely to continue in the same way for several months. We have men enough, however, as the demand will not be sudden, and therefore it is an easy matter to get miners whenever they are wanted."

Placer.

WILL PUT UP A MILL.—The Bella-Union quartz claim adjoining the Pike Bell five-stamp mill on the American river, assays rich ore. Such a good showing is made that the company is putting up a mill. They have enough ore in sight to pay all expenses. The Pike Bell adjoining is milling rich ore.

Plumas.

THE FOUR HILLS.—*Independent:* Operations will be resumed at the Four Hills quartz mine this summer. This mine has not been operated for some years.

Riverside.

A FINE LEDGE OPENED.—*Record:* A well-defined ledge has been found in the Golden Chariot mine, six miles west of Perris. It is the intention of the owners of the mine, Messrs. Day & French of Redlands, to sink on the ledge until a supply of water sufficient to run a mill is found. The Golden Chariot is an extension of the Santa Rosa, and 150 feet higher on the surface. Water was found in the Santa Rosa at a depth of 200 feet, therefore it is computed that a shaft 350 feet on the Golden Chariot will be necessary to develop an adequate supply of water. The Golden Chariot ledge is said by many to be the mother lead of all the Pinacate mines.

THE SUNNYSIDE MINE.—This mine, located three and a half miles southeast of the Good Hope, is now down forty feet and has a three-foot ledge assaying $25 in gold and $4 in silver to the ton. It is a promising property and grows richer as depth is attained. The statement that $100 and $200 ore had been found in the mine is entirely erroneous. The mine is a good one, but statements to the effect that $200 ore is being taken from a ledge that produces ore worth only one-eighth of that amount are discouraging to mining districts, and their truth should be enquired into before they are given to the public.

San Bernardino.

A RICH STRIKE REPORTED.—A private letter reports a rich strike in the Rose mine in Lone Valley, made on the 450 ft. level, which was drifted on for 45 feet and sunk on for 55 feet. There is eight feet of high grade ore, some of it going $200. The rock is limestone and mica schist. The new strike appears to be in the west end of the mine.

Shasta.

GENERAL MINING NOTES.—*Democrat:* Ellery Brothers, at French Gulch, ran their Huntington mill two days last week and cleaned up $500. This makes $2180 from seven days' run. The ledge has widened from four inches to three feet.

The Gladstone Company keeps the mill going steadily. The Washington also shows a fine ore body.

A bunch of high-grade copper ore has been found near Whiskytown.

Col. Connors has struck a very rich ledge of coarse gold and free-milling gold on Boulder creek.

At Muletown a Mr. Haskall has bonded nearly everything in sight, the Dobelin and Whit George claims being among the number.

Fred Grotefend has bonded the Afterthought and Donkey mines at Furnaceville. An Eastern party talks of erecting antimony works there.

It is rumored that the Northern Light and Bully Hill properties are sold to a Los Angeles party. Mr. Book is the middleman.

It is also rumored that R. M. Sæltzer and Judge Reed have bonded the Winthrop. A party has also bonded several claims carrying base metals near Bass' store on Pitt river.

At Iron Mountain the company now have about 100 men at work. The going wages are $1 a day and grub.

R. G. Hart, in Old Diggings, talks of putting in twenty more stamps.

J. M. Gleaves has just finished surveying the Central group for a patent.

Charley Dozier of San Francisco has just finished sampling the Hendy property in Old Diggings, and has shipped a carload of ore to Frisco.

W. P. Miller has 200 tons of ore out and is hauling it to his mill at Middle Creek.

Siskiyou.

MINING NOTES.—*Journal:* The Espey Mining Co. has completed the extension of the electric light plant ditch at Shasta river, and securing foundation for the pump is progressing rapidly, with most of the machinery hauled to the ground. As soon as the pump is set in place, the extension pipe will be laid to the top of the hill, and a large flume built at the same time from top of hill southward to the claim near the town of Hawkinsville. It is expected the company will be able to commence work with giants and in sluicing before the 4th of July next.

The Schroeder mine on Deadwood mountain is being worked and the mill kept well supplied. There is a good deal of snow yet in the vicinity of the mine, but will soon be gone.

NEW STAMP MILL.—The new stamp mill of the Black Jack Mining Co., at Hornbrook, is finished, and about thirty men will have employment there this summer.

Sierra.

MINING PROPERTY ATTACHED.—Downieville *Messenger:* A heavy attachment was levied upon the Gold Bluff Mining Company's property last Monday afternoon. We understand that Mr. Hobbs, on behalf of the electric company which furnished the electrical machinery to the mine, filed the first lien, whereupon John Costa put on an attachment for about $10,000 due him. This was quickly followed by the workmen levying a miner's lien upon the property, which has since been assigned to John Costa, he buying them all in. The total attachment will aggregate nearly $20,000. The cause of this cannot be attributed to the failure of the mine's production, but is no doubt due to an endeavor on the company's part to erect costly outside improvements, and the failure of the stockholders, who live in New York, to respond.

NEVADA.

Lincoln.

PHŒNIX MILL.—*Record:* The mill of the Phœnix Reduction Co. at Bullionville is now running steadily on a lot of ore from the April Fool mine, in Ferguson district. After this is run through, a lot of gold-bearing rock from the Flagstaff mine will be worked there.

Lyon.

A PERMANENT CAMP.—Dan De Quille: Silver City is the mother gold camp of Nevada. Work began on the gold-bearing veins of that place thirty-five years ago, and has been in constant progress ever since. Miners who took hold of mines in Silver City in 1859-60 are still there, and holding on to their ground. They have married, reared families and are grandfathers; still their mines do not fail them. Old as is the camp, about as many new discoveries are being made there as anywhere in the country. The permanency of this old camp should encourage all who are interested in the gold mines of Nevada. In every part of the State where paying gold mines have been found, the veins still pay. Barren spots may be found once in a while, but no mine is all "bonanza"—some "borrasca" must be expected.

THE DEAL PROBABLY OFF.—Salt Lake *Tribune:* Charles Legg of Bingham, who went to Elko, Nev., to examine the mines of the Octorora group for Salt Lake parties, has returned, but has not yet filed his official report. He has stated to his clients that the property is not as good as represented, and it is believed that the prospective deal is now off.

SILVER STAR DISTRICT.—*Enterprise:* The Brown mine is the only developed property in the camp. The average grade of the ore is $100 per ton. There is now some $375,000 worth of this ore in sight. The other claims all have pay ore in sight but none is of so rich quality as that in the Brown, the general average apparently being from twenty to forty dollars. There are ten or twelve well defined ledges, but the ledges, with the exception of the Brown, are apparently small, none having been developed.

There are situated on two sides of the mountain. Those on the east side where the Brown ledge is owned, from east to west, and those on the west side from north to south.

There are at present 120 men in the camp. The most of the claims are being worked by lease-holders, and while some of these are making money, they are the exception rather than the rule. The reasons that lease-holders are not as a rule prospering at Silver Star is that the ore is of comparatively low grade, and they having limited capital have much to contend with.

Prices at Silver Star are exorbitant. It costs $6.50 per ton to mill ore in lots less than fifty tons and $5 in lots of fifty tons or more, and few of the lease-holders can wait until they have accumulated this amount. It costs from $1.50 to $3 per ton to transport this ore from the mines to the mills. There being no roads, it all has to be packed on mules.

Lumber costs $40 per thousand. There is plenty of water on the east side of the mountain to run the Douglass Company's mill; but the Douglass Company controls it all. Thus it will be seen that leasers, after paying ten per cent for their mines, have much to contend with.

THE MINING OUTLOOK.—The mining outlook in this State is very promising at the present time. Silver Star district will be a fine camp in the near future. They are talking of mining properities in that district way up in the hundred thousand figures, and the grass roots have hardly been disturbed yet. White Horse district, in Humboldt county, is attracting attention, while the placer mines just north of Reno promise to develop into something worth having, to say nothing of the quick-silver, gold and silver prospects about twenty miles north of Reno. Kennedy district is under a cloud just now, but it has a silver lining and much may be expected of that camp this season. They are all gold prospects, too.

MASON VALLEY GOLD.—Dayton *Times:* W. H. Spragg was in from Mason Valley the first of this week and from him we learn that the new gold discoveries in the upper end of the valley, about six miles from Yerington, are opening up very well. The three principal claims in the district so far are the Mountain Chief, Silver Leaf and Jack Wilson. The ledge in the Mountain Chief is all of two feet wide as far as has been uncovered, and it can be traced on the surface for over a distance of 1,500 feet. Assays from this claim go $150 in gold and $35 in silver. The other two claims, which are farther down the mountain side, are also showing up some good ore, and the ledges are, so far as known, from six inches to three feet in width. Assays from the Silver Leaf go from $7 to $115 in gold and from $4 to $30 in silver. Assays from the Jack Wilson go from $25 to $213 in gold and from $2 to $12 in silver. There is enough ore in sight in the Silver Leaf and the Mountain Chief with what little work has been done, to keep a ten-stamp mill running for a year or more. Messrs. Spragg and Martin, who own these claims, are, in company with a millwright named Nixon from San Francisco, putting up a horse-power arrastra, and will have the same completed and working ore next week. The ore will only have to be hauled about half a mile. These mines are liable to prove bonanzas to their owners at no distant day.

ARIZONA.

LOCATING MINING CLAIMS.—*Journal-Miner:* The passage of the mining law by the recent Legislature seems to have given quite an impetus to the location of mining claims. The law does not take effect until July 1, 1895, and locations can be made previously without one being compelled to do a certain amount of development work prior to recording. During the first two days of the present month forty-three location notices were filed for record, twenty of which were for lithograph stone, and up to noon of the third day eight had been filed for record, making a total of fifty-one notices for the two and a half days.

VICINITY OF YUMA.—A good road has been built by the miners from Blaisdell station to Thomas Camp. The ore there ready for shipment will soon be hauled in to the station and sent to San Francisco.

There are three carloads of tank material at Aztec awaiting transportation for the Harqua Hala Gold Mining Co., to be used in their new plant for working the tailings by the cyanide process.

Seven ounces of free gold have been cleaned up from the waste of the Arizona and Half Moon claims at Thomas Camp. These properties are yielding shipping ore.

"An expert is said to have lately visited the Queen mine of the Golden Cross Company, and estimated the amount of ore in sight at 2,000,000 tons worth $6 a ton. The Queen is something of a blanket ledge, lying at an angle of about 30°." This is from the Yuma *Times.*

Grading has been resumed on the site for the sixty-stamp mill at Golden Cross. Some of the timbers will soon begin to arrive. The new site is well up on the side of the hill and affords plenty of room for tailings. When the sixty stamps are ready to run, the present forty-stamp mill will be set up alongside of them, making 100 stamps in a string.

AROUND JEROME.—The Jerome *Chronicle* says: Charles Ward has bonded the Copper Matte group of mines, consisting of four mining claims, as follows: Copper Matte, Black Hawk, Wizard and Daunted. He has interested L. P. Drexler in the property, who purchased a two-thirds interest, and Mr. Ward a one-third for himself. Mr. Ward says they paid $10,000 for the whole group. The claims are on what is called the "south end" lode, and two and one-half miles south of Jerome. The development done on them consists of a forty-foot shaft, showing good ore as it went down. At the bottom the ore is of better grade. The shaft is still in ore which carries gold, silver and copper. Mr. Ward informs us that they intend to put up a steam hoist, build a road and sink the shaft deeper. The future will depend upon what Mr. Drexler's views may be after he arrives from San Francisco and makes an examination of the property.

BRITISH COLUMBIA.

THE JOSIE.—Nelson *Tribune:* R. E. Lemon is either lucky or unlucky. Last year when he sold his interest in the Josie, a Trail creek prospect, for $7,000, he thought he was playing in good luck. Were he to see the Josie today, he would think he played in bad luck. The whole width of the lower tunnel is in ore, and the walls are as well defined as those of a plastered house. The ore body is between five and six feet wide, the ore is clean, and the grade is higher than the ore from either the Le Roi or War Eagle. The face of the tunnel is nearly 200 feet from the surface, and experts reckon the Josie to be worth $100,000.

LE ROI WILL MAKE THINGS HUM.—At a recent meeting of the board of trustees of the Le Roi Mining Company, Manager I. N. Peyton was instructed to purchase immediately for the use of the company an additional boiler of 100-horse power and a new hoist of 100 tons per day capacity. The company now has on its dump ready to ship 1000 tons of ore, and intends to produce and ship fifty tons per day during the summer months, and additional hoisting machinery is necessary to take care of the increased output. The company is giving employment to all freighters who make application at the mine, and could use ten or fifteen additional four-horse teams.

COLORADO.

Cripple Creek.

C. O. D. MINE SOLD FOR $600,000.—The C. O. D. mine, in Poverty Gulch, has been sold for the reported sum of $600,000. The sale which has been pending for a short time only, was ratified this week, when $25,000 of the purchase price was deposited in the First National Bank of Cripple Creek in the name of the original owners.

The check was signed by H. R. Lounsberry of New York, who conducted the purchase, and who is supposed to be acting for a party of New York men and also largely for himself.

The C. O. D. mine was the property of Troy, Burke, Sutt and Penrose. Ten days ago, they say, they gave an option on the mine for ten days at $600,000. They now declare they had no idea it would be taken up in that short period of time, and therefore made no preparations for turning the property over to the new owners. The option expired, and in accordance with its terms the $25,000 was paid in the bank and the final papers signed. All the money is to be paid by July 1st.

IDAHO.

PLACER MINES SOLD.—Caldwell *Tribune:* F. Stounenberg has sold to E. T. Staples, of Payette, a half interest in the Colorado Bar

and Big Bar placer mines; consideration, $2,000 each. The mines are situated on Middle Boise river, 100 miles east of Caldwell.

A VERY BIG STATEMENT.—Lemhi *Republic:* A very rich strike is reported from the Yellow Jacket by the Columbia Company. A 700,000-ton body of ore has been uncovered on the Cleveland and Estevan claims. It is free milling and will yield in the neighborhood of $12 a ton.

THE BUNKER HILL AND SULLIVAN.—At a meeting of the Bunker Hill and Sullivan Company, at which several large stockholders were present, recently held at the office of the company, it was decided, in view of the present situation, to further curtail expenses, and that the company would not consider the subject of starting up at all for the present, nor until such time as they received full assurance that when they do, the community will allow them to manage their own business, according to the company's own best judgment. The company further resolved to pursue the policy it has always followed, of not making any compromise with any association whatever, in order to be able to run the mine. When they do start up they intend to take care of their friends and those who have stood by them heretofore, giving them, all conditions being equal, preference over those that have in the past tried to interfere in the management of the company's own private affairs. The company for some time past has been looking into the matter of installing sinking machinery, and also machinery for recovering part of the mineral that at present goes into the tailings. As the installation of all this machinery involves an expenditure of a large amount of money, the whole matter will be held in abeyance until the company is assured by the community that it can manage its own affairs and run the mine in its own way for a period of at least three years. To sum up, the company will not go to the expense of starting up until it is absolutely certain that the community will hereafter not interfere with the maangement of the company's business, nor drive out of town American citizens who may desire to work for the company.

The following proposition is being circulated for signatures:

"We, the undersigned, citizens of Wardner and Kellogg, in consideration of the extremely low prices of lead and silver now ruling, and in further consideration of the fact that the cost of living has decreased, believe that while these low prices continue, $3 per day for miners and $2.50 per day for laborers, are fair and just rates of wages. We further believe that the Bunker Hill and Sullivan Mining & Concentrating Company has the same right to manage its own affairs as we have to manage ours; and we hereby pledge the company our cordial support in its determination to pay no higher wages while the prices of lead and silver are so low."

THE BUNKER HILL'S OFFER.—Twenty-five of the business men of Wardner and Kellogg called on Mr. Corning and Mr. Bradley of the Bunker Hill and Sullivan office, Sunday evening, March 31, to consider the question of starting the mine. On being asked under what circumstances they would start, Mr. Corning replied: "We will start the mine providing the citizens of Wardner will stand by us. We ask no man to shoulder a gun, and we will pay $2.50 and $3 for labor, and as soon as lead and silver advance we will pay more. Furthermore, we want it plainly understood that we will not recognize any labor organization whatever."

A BIG PROPOSITION.—*Review:* An immense vein of rich galena ore was recently uncovered in the Helena and Frisco mines in the Coeur d'Alene country. The property is owned by S. T. Hauser, A. M. Holter, John T. Murphy, A. J. Seligman, Peter Larsen, A. M. Esler, H. Barbour and E. W. Knight. These gentlemen have invested about $1,000,000 and have taken out about $1,500,000 in cool cash. The find is reported to be the greatest ever made in a galena property, and was at first doubted by the Helena owners. The new ore body was encountered in a drift eighty feet from the 100-foot level, where a body of solid ore sixty feet wide was exposed in a crossent. The pay streak as shown in the shaft and drift from the surface extends 800 feet along the vein, as demonstrated in prospecting shafts.

A full equipment of the most modern machinery has been ordered for the mine, all of which will cost in the neighborhood of $40,000. The equipment includes a compressor, which will be the largest in America, running as it will between forty and forty-five drills. This machinery will be in position and full operation on or about August 1. When the new machinery is in and the mine being worked to the full capacity of the mill the profits will amount to over $25,000 per month.

MONTANA.

THE GOLDEN SUNLIGHT MINES.—*Review:* The American Development and Mining Company have taken full charge of the Golden Sunlight group of mines near Whitehall, and intend working it on a larger scale than ever before. The closing down of this property two weeks ago by the New York company threw quite a shadow of disparagement over the Whitehall district and for a while the situation looked quite dubious. Bernard McDonald, president of the A. D. and M. Company, went over there last week and took charge of the property after the New York syndicate had thrown up their bond and lease. Everything on the premises, including machinery, buildings and railroad improvements, reverted back to the original owner. The New York company had the property bonded for $500,000, upon which they had paid $165,000, with the fourth payment due in April. This they forfeited when due, and no time would be given them on an extension.

The American Development and Mining Company will now go ahead with the work themselves with James H. Henley, formerly superintendent at the Granite Mountain mines, as the manager of the property and one of its trustees.

OREGON.

BAKER.

RICH STRIKE AT THE VIRTUE.—*Democrat:* There was another rich strike made at the Virtue mine yesterday and from all reports it is the most extensive gold deposit unearthed in this section for a long time.

Persons who were at the mine yesterday and who came to town report that during the time they were at the mine the miners were coming up from the shaft with candle boxes filled with gold, seemed with quartz.

The new find was uncovered in the crosscut tunnel from the 300 foot level, it is certain that the $20,000 monthly output with twenty stamps will be considerably increased from this time on.

UTAH.

A NEW PROCESS.—*Tribune:* William Kelly, of Ophir, has discovered a process for treating gold, silver and lead ores, which saves ninety-five per cent of the values, at a cost, he claims, of $2.50 per ton.

WYOMING.

A GOOD MINE.—Bart Bissaca, of Beulah, is said to be the owner of a gold mine that shows $780 to the ton in gold, with a good body of such ore in sight.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from David Croft, in the Gold Deposit mine, near Kelsey, El Dorado Co., to deposit tailings in an old hydraulic pit; from Wm. F. Coe, in the Railroad Placer Mine, near Placerville, El Dorado Co., to deposit tailings behind dams in Spanish Flat Ravine; from J. C. Day, in his mine near Georgetown, El Dorado Co., to impound tailings in an old hydraulic pit; from John A. Bowles, in the Independence Mine, near Brownsville, Yuba Co., to impound tailings behind a dam in Letson Ravine; from Wm. Henning et al, in the Iowa Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jas. Ward & Wm. McDonald, in the Tiger Mine, near Forest Hill, Placer Co., to impound tailings behind a dam in a ravine; from Jos. J. Hoffman et al, in the Hard Times Mine, Bath, Placer Co., to impound tailings in an old hydraulic pit; and from Wm. & Wm. J. S. Bacchi, in the El Dorado Placer Mine, Garden Valley, El Dorado Co., to impound tailings in ravine below the mine, gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, on April 22d, 1895, at 1:30 P.M.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

Electrical Progress.

Large Guns as Magnets.

Some months ago the PRESS published an interesting account of an unusually large magnet constructed of two fifteen-inch guns at Willets Point, N. Y. The subject has attracted considerable attention. In the current number of *Cassier's Magazine* is an article with the above captiou, written by Lieut. King, in which he says:

The idea of constructing a huge "gnn magnet" was suggested to the writer some twenty years ago by seeing two fifteen-inch guns lying side by side at the United States Engineer School at Willets, New York; but as there was then no snitable insulated wire at haud, and as no means were available for generating a powerful electric current, nothing was attempted at that time. In 1888, however, the accumulation of several miles of condemned torpedo cable and the presence of some large dynamos brought the subject forward in a still more suggestive and practicable form, and the experiment was tried.

The guns, weighing 50,000 pounds each, were placed side by side and connected at the breech by a pile of railway bars. Coils of insulated wire, some eight miles iu all, were placed around the muzzles of the gnns, and an armature, 7½x11½ inches in cross section, was made of wrought-iron plates bolted together.

When the current was turned on, it was not only found that a magnetic field of unprecedented inteusity was formed, but an exceptional opportunity was presented for studyiug the pheuomena of electro-magnetism. The lines of force could be traced to a great distance. A pnll of 20,600 pounds was required to detach the armature, and four 320-pound projectiles were suspended like a string of beads from one of the guns.

In more recent experiments with a single gun, wrapped with about ten miles of wire, and having the maguetic circuit completed by a pile of heavy iron plates, the pull required to detach the armatnre was 44,800 pounds, and five of the projectiles were supported from the muzzle. It is, perhaps, needless to say that the extravagant statements recently circulated about this magnet are without foundation. It was never intended "to derange ships' compasses" at *any* distance, and it certainly could not do so at a range of "six miles," nor could it pull vessels out of the water or arms out of the hands of soldiers. Such statements would refute themselves if it were not for the fact that electricity has, for several years past, been doing such unexpected things that even scientific men hardly dare to say that anything claimed for it is impossible.

In this utilitariau age the first question asked is, "What is a thing good for?" and, in this case, the answer is, "To study electro-magnetism on a much larger scale than has hitherto been attempted." It is well known that all physical laws can be better understood by studyiug extreme cases as well as intermediate ones, and in this iustance several results have been observed that have escaped uotice in ordinary experiments.

At a distance of about seventy-oue feet the field of this magnet is equal to the earth's field, or, in other words, it will deflect the needle 45° at that distauce. At a distance of 200 feet the deflection is 3°. At about 7½ inches from the muzzle of the gun there is a neutral point at which a small piece of iron is neither attracted nor repelled. If placed nearer the gnu, but in its axis, it will be thrown out with some little force, sometimes as much as two feet, and then drawn back obliquely to the side of the muzzle. No perceptible effect can be detected on the nerves or muscles of the human system, although the lines of force sent through the head or heart are strong enough to cause iron bars, spikes, etc., to stand ont like the quills of a porcupine.

Theoretically, such a stroug magnetic field should check or "damp" the vibratious of metallic strings; but iu the few experiments tried, no such effect was perceptible. Three strings of a sonometer, one each of iron, brass and twine, were all tuned to "b flat," but when sounded together in the magnetic field, close to the muzzle of the gun, they were still in unison as nearly as could be detected. Neither was there any perceptible effect on light. For the purposc of testing this a transit was set about thirty feet from the magnet and sighted, at a well-defined mark several hundred feet beyond it, the line of sight passing only a few inches from the magnet. When the current was turned on, no chauge whatever was observable in the appearance of the object. In other words, the rays of light were not bent.

These last three results are of a negative character, but they are conclusive as far as they go. In these experiments there were about 5250 tnrns of wire around the gun, which, with a current of about twenty-one amperes, gave over 110,000 "ampere turns." The cross section of the cast-iron core varied from 300 square inches at the muzzle to about 1500 square inches at the largest place. The length of the gun is about sixteen feet, and the coils of wire cover about one-half the length.

A Tremendous Light.

The idea of an electric light which, fed by a current from a dynamo actuated by a forty-horse power engine, and giving 7,000-candle power can have its illuminating power intensified 35,000 times, is not easy to grasp. It means the production of a stream of light of about 250,000,000-candle power, aud it is no wonder that the announcement that snch a light is about to be used in this country has been received with some incredulity in Europe. This is the efficieucy of the light which will be shortly erected at Fire Island for the illumination of the adjacent coast and the protection of the fleet of ships eutering New York Harbor. A remote suggestion of the power of this lamp may be arrived at by bearing in mind that an ordinary oil lamp is about thirty-eight or forty-candle power, and then trying to imagine the combined beam of 3,000,000 lamps. The ordinary electric street light may be put down at 100-candle power. and 250,000 of these would about represent the strength of the Fire Island light.

The most powerful oil lamp yet made is supposed to shine ont on a clear night for a distance of thirty-five or forty miles, but the new light will flash its welcome rays to the coming European liners when they are 120 miles away. The light revolves rapidly and throws out its beams with the inteusity the speed of lightning. The motive power which actuates it is a simple clock-work arrangement contained in a box two feet square, and although the revolving portion of the light weighs fifteen tons, the mechanism controlling it is so delicate that the pressure of two fingers will turn it. The value of this marvelous lamp can only be determined by practical working, but it promises to represent an immense stride in the science of coast lighthouse illumination.

IN CHICAGO the mails are now sent from the postoffice to the Illinois Ceutral depot by electricaily propelled cars, rnnuiug over the roofs on a three-eighths-inch steel cable carried by iron brackets on posts. The little aluminium cars carry seventy-five pounds each. The current is transmitted by a trolley running on a wire parallel to the cable.

THE result upon prices of the reduced consumptiou of metal is illustrated that a recent electric lighting scheme in Londou has been carried out at a saving on the estimate on copper alone of £6000.

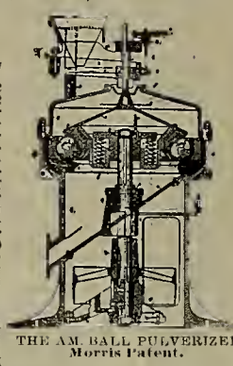
First Prize and Gold Medal Awarded by World's Fair, 1893.

Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O., Jan. 25, 1894.
The American Mining & Milling Machinery Co., Cleveland, O.:
GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4⅞ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows LESS; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with LESS than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,
CLEVELAND IRON ORE PAINT CO.



THE AM. BALL PULVERIZER. Morris Patent.

THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

The Columbian Exposition Medals.

Exhibitors at the Columbian World's Fair in 1893 are growing tired of waiting for the promised medals and diplomas. Information given out quite recently assures the public that the Bureau of Awards is alive, though moving slowly, and that there is good reason to believe the awards will be distributed before the close of 1895.

The Director of the Mint says the medals will be ready for distribution about June 1st. The superintendent of the Bureau of Engraving and Printing says the diplomas are about finished. Though the diploma holds the spirit and letter of the award, the medal is the symbol, and the two must go together. Therefore, allowing a small margin of time, which it is always safe to allow the Bureau of Awards, the sending out of medals and diplomas will hardly begin before July. But it is encouraging, after all the bother and delay over the design, to know that the medals are really under way—up in Connecticut, where artistic work has a wide range, from a wooden nutmeg to a Waterbury watch. In fact, it is a Waterbury firm that is turning out the medals, according to contract let by the Secretary of the Treasury—not to the highest bidder, but to this particular firm, which is to furnish 23,700 bronze medals for $30,000. If, however, any exhibitor should prefer a gold medal, he is authorized by the Congress of the United States to have one, providing he pays for the gold himself. Otherwise all the medals will be of bronze, also authorized by Congress, and perfectly alike, except in the names of exhibitors inscribed on them.

De Lamar in California.

Not content with big mines in Nevada, Colorado and other places on this side of the Sierras, it seems that Mr. J. R. De Lamar now desires to try his luck in California. He wants to get hold of a big property in that State. He does not care for a small vein. If he can find something really "big," he is ready to expend a large amount of money for its development. He will probably be able to find what he wants in the "Golden State," as in numerous places over there are to be found "propositions" so big that no man has yet put in an appearance who was possessed of sufficient "sand" and coin to tackle them. Particularly is this true of gravel deposits and mountain drift diggings, but one may also find undeveloped auriferous quartz lodes of mammoth dimensions. In almost every section of California are to be found miners who for years have been holding on to quartz and gravel claims so big that they are themselves unable to do anything with them. Men of means and mining knowledge need not go to South Africa or West Australia in order to find some big thing to tackle. There are here at home, in the midst of civilization and within easy reach of all necessary supplies, plenty of undeveloped mines. And much in regard to the nature and richness of these mines may be judged from what is to be seen in the producing mines already opened in the same gold belt.—Dan De Quille, in Salt Lake Tribune.

Metal as a Building Material.

It is well within the memory of many persons when metal as a building material was practically unknown. But within a few years building has been almost revolutionized by the use of metal in various forms and for various purposes. Iron beams, columns, girders, rafters and window sashes have come into use, and now we are to have as a regular addition to our list a great variety of stamped-out sections. These have heretofore been made mostly out of galvanized iron or some composition of the spelter sort, or, in fine and high-priced work, bronze has been employed. Steel is, however, found to answer all demands far better than any other metal used for this purpose. Door and window casings will be made of metal, and, indeed, almost all parts of a house may be constructed of something besides wood. With paper-pulp doors and floors, metal frames and finish, slate or tin roof, and Portland cement or concrete walls, our houses may in time come to be actually fireproof, as they have for a long time unjustly claimed to be.

Luminous Paint.

The formula for luminous paint, about which so much has been said, is as follows: Take oyster shells and clean them with warm water; put them into the fire for half an hour; at the end of that time take them out and let them cool. When quite cold pound them fine and take away any gray parts, as they are of no use. Put the powder into a crucible, in alternate layers, with flour of sulphur. Put on the lid and cement with sand made into a stiff paste with beer. When dry, put into the fire and bake for an hour.

Wait until quite cold before opening the lid. The product ought to be white. You must separate all gray parts, as they are not luminous. Make a sifter in the following manner: Take a pot, put a piece of very fine muslin very loosely across it; tie around with a string; put the powder into the top and rake about until only the coarse powder remains; open the pot and you will find a very fine powder; mix it into a thin paint with gum water, as two thin applications are better than one thick one.

This will give a paint that will remain luminous far into the night, provided it is exposed to the light during the day.

PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, April 18, 1895.

The news of peace between China and Japan is secondary to the world-wide attention given the silver question and its immediate relations thereto. Among other terms of peace are the payment by China to Japan of 200,000,000 taels. It is to be borne in mind that a "tael" is not a coin, but a weigbt. The Chinese currency system is based upon a certain weight of silver, and not upon the number of a standard coin. Thus, although the currency consists of "cbopped" Mexican dollars, *i. e.*, Mexican dollars defaced by the mark of, say, a blunt nail, yet $1000 Hongkong currency does not consist of 1000 of these defaced dollars, but of 717 taels' weight of them. If the coins are new, 1000 by count weigh about 72½ taels; thus 717 taels' weight would consist of only about 995 pieces. The tael equals 579.84 English troy grains. Any one presenting a check or note for $10,000 at a bank, and wishing to receive coin, would have weighed out to him 7170 taels weight of chopped dollars, and would receive, more or less, 9950 pieces. This system is not so inconvenient as it seems. Europeans, in their small private transactions, by means of notes, checks and small change, manage to avoid altogether the weight system. The 200,000,000 taels indemnity represent about $290,000,000 in Mexican silver dollars. Though not directly and definitely stated, it is generally assumed that the indemnity will be paid in silver. The extreme probability of this has doubtless been the cause of the recent advance of 13 per cent in the price of silver. That such temporary demand would only cause a temporary appreciation in the price is evident; but it is believed that tbere is to be a steady development of Chinese industrial enterprise, a greater inflow of silver to the Orient and a permanent steadiness in silver quotations at a price beyond present quotations. Silver may go to 70 and hover there before mounting higber, but that its upward flight has only begun is asserted by many who claim that the present discussion between men of all parties and no party at all will assuredly result in a renewed apotheosis of the white metal.

This question of a "market for silver" has been wrongfully assumed to be like the tariff —a sort of protected industry discussion—and that salvation lay in "sound," i. e. gold, currency, tbe matter being of greatest interest to a few scattered silver producers in the west half of America. The bulk of the American people are finding out that they have more real interest in the matter than "the silver baron" or the miner on the mountain side, and that, like the man in the wagon drawn by the runaway team, he "can ride as fast as tbey can run." The country needs silver coinage, and the prosperity or poverty of the men who produce the silver is only a small factor in the main problem—national life.

Mining Share Market.

SAN FRANCISCO, April 18, 1895.

Lower prices prevailed in the early part of the week, and all business was done on a declining scale, the result of continued lack of interest on the part of the former purchasing public. Permanent advance in the price of silver would help out a present weak and wobbly market.

The following illustrates the changes of the week:

Notices of Recent Patents.

Among the patents recently obtained tbrough Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

PARASOL AND FAN.—Mathias Stocklmeier, Los Gatos, Cal. No. 536,707. Dated April 2, 1895. One-half assigned to Charles A. Bronaugh, of the same place. This invention is designed to provide an article which may be converted into an ordinary parasol, standing at right angles with the handle, or a carriage parasol where it lies parallel with the handle, or a fan, or it may be folded entirely into such small compass as to be carried in the pocket or handbag. It consists of a series of elastic ribs having the outer covering fastened thereto, and a pin passing through the meeting ends of these ribs, forming a common center about which the ribs are allowed to turn so that they may all be folded up at one side or opened out to form a complete circle, the material of the covering being separated adjacent to one of the ribs, and the two ribs which come together having a fastening by which they may be locked so as to form a complete parasol. Tbe handle is jointed near the top, so that it may be turned by moving a sliding catch to allow the parasol to lie sideways along the handle, and thus adapting it for carriage use. If it is desired to use it as a fan, the two adjacent ribs may be disconnected and the device closed up to one-half of the circle lying along the side of the handle, and making a convenient fan. The handle telescopes so that it may be lengthened or closed as desired, and when the article is to be packed, all the ribs may be closed alongside the handle and the handle reduced to its shortest length. The device forms an exceedingly convenieut article for ladies' use.

CONNECTION FOR FLUSHING DRAIN-PIPES OF SINKS, WASHBASINS, ETC.—Fred. B. Vinter, San Jose, Cal. No. 536,769. Dated April 2, 1895. The object of this invention is to provide a simple and readily adjustable means for connecting a flushing or forcing pump with the drain or tbe waste pipe, wbereby the latter may be cleansed or opened out when clogged, in an easy, thorough and effective manner, the work being done by one man instead of two ordinarily employed. The device consists of a plate or base adapted to fit within tbe vessel directly over the mouth of the drain or waste pipe, said plate or base having an internally threaded opening, and a washer or gasket under it to form a tigbt joint; means for securing and tightening the plate or base to its seat, and an internally threaded nipple fitted to the base and adapted to be screwed to the internally tbreaded opening therecf for the attachment of tbe hose of a force pump.

CONNECTION FOR FLUSHING DRAIN-PIPES OF SINKS, WASABASINS, ETC.—Fred. B. Vinter, San Jose, Cal. No. 536,770. Dated April 2, 1895. This invention has the same object as the preceding one, and it consists of a different means of securing the parts in place, namely, a nipple passing througb the central aperture of the plate or base, and having catch lugs on its lower end adapted to engage the cross-bars of the strainer.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDINO APRIL 9, 1895.

537,037.—TUBE TESTER—T. W. Heintzelman, Sacramento, Cal.
537,038.—SAFETY VALVE—T. W. Heintzelman, Sacramento, Cal.
537,153.—SASH HOLDER—L. A. Heinzerling, Monte Cristo, Wash.
537,294.—GAS BURNER REGULATOR—J. Kraker, S. F.
537,162.—CAN—John Lee, San Mateo, Cal.
537,346.—CONNECTING ROD—F. F. Maag, Beaumont, Cal.
537,056.—HOP PICKER—M. Marsa, North Yakima, Wash.
537,360.—STATION INDICATOR—Murray & Krasky, S. F.
537,313.—PRESERVING FRUIT—A. D. Shepard, S. F.
537,314.—RIVETING MACHINE—J. I. Smith, Chico, Cal.
537,082.—TAPE MEASURE—C. Smart, Turlock, Cal.
537,257.—GOLD SAVING APPARATUS—B. M. Whiting, Spokane, Wash.
24,176.—BADGE DESIGN—C. G. Tingry, Portland, Or.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

WANTED!

$2500—Wanted, a competent and honest quartz mill man, with above sum, to take half interest in custom quartz mill, permanent and desirable.

$5000—Wanted, a competent and honest quartz mill man (assayer preferred) to take interest in a custom quartz mill, chlorination works and a group of developed mines.

Both of these investments are safe and desirable, and invite investigation. For particulars, address

G. B. ROBERTSON, Attorney-at-Law,
YREKA, CAL.

A SPECIAL MEETING of the stockholders of the Julia Consolidated Mining Company will be held at the office of the company, room 56, No. 309 Montgomery street, San Francisco, California, on FRIDAY, the 3d day of May, 1895, at the hour of 1 o'clock, for the purpose of considering what disposition shall be made of stock now in the treasury of and belonging to this company, and the transaction of such other business as may come before the meeting. Transfer books will close on Tuesday, April 30th, at 3 o'clock P. M.
J. STADTFELD JR., Secretary.

Assessment Notices.

BRUNSWICK CONSOLIDATED GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley Mining District, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 20th day of March, 1895, an assessment (No. 8) of Two cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room 56, Nevada Block, San Francisco, California, or to the Treasurer, J. J. Halpin, 57 Broadway, room 87, New York City, State of New York, on or before the 20th day of April, 1895.

Any stock upon which this assessment shall remain unpaid in San Francisco, on the 20th day of April, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.
J. STADTFELD JR., Secretary.
Office—Room 56, Nevada Block, San Francisco, California.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 20th day of March, 1895, an assessment (No. 18) of Ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 69, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 15th day of May, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.
ALFRED K. DURBROW, Secretary.
Office, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

OVERMAN SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Gold Hill, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of April, 1895, an assessment, No. 73, of ten cents (10c.) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, No. 414 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 11th day of June, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. D. EDWARDS, Secretary.
Office—No. 414 California street, San Francisco, California.

And all kinds of
MACHINERY FOR MINING PURPOSES.

Flour Mills, Saw Mills and Quartz Mills; Machinery Constructed, Fitted Up and Repaired.
FRONT STREET, Bet. N & O.,
SACRAMENTO, CAL.

Coast Industrial Notes.

In addition to the launches recently built, the Union Gas Engine Co. are building three for Australia.

A large force of men is at work on the Rio Verde, Arizona, canal and storage reservoir. The entire work will cost $2,000,000, and is to be finished in three years.

The Zindorf Construction Company, of Seattle, Wash., has incorporated with $70,000, to construct railways, bridges, etc. The incorporators are M. P., H. I. and M. Zindorf.

The Pelton Water Wheel Co. are sending a 200 H. P. plant to Kioto, Japan, there to be used in operating a street railroad system. They are also building an electric-power plant for Guatemala residents.

The Hayward-Lane mining properties at Silver Bow, Alaska, are having put in place the new mill, etc., recently shipped from the Union Iron Works. Francis Smith & Co. are sending up several thousand feet of iron pipe.

The Union Iron Works has secured the contract for the immense new hoisting plant for the Anaconda, Montana, mine. The Anaconda has everything on a superlative scale and the new machinery will be second to none in that State.

W. E. Lindsay, at his marble works in Antelope valley, Nevada, last week cut out by machinery a block of marble six feet square and eleven feet long. The block contains 396 cubic feet and weighs 80,000 pounds. It is the largest solid block of marble ever cut out by machinery on this coast.

It is stated in Los Angeles papers that Stein Bros., the proprietors of the Monarch Distilling Company of Chicago and Owensboro, Ky., are making arrangements to put in a $1,000,000 plant in that city. President Stein is now there, and has purchased property which is said to be intended as ground for the plant.

The Market Street and Castro Street railway lines were each supplied with a new cable this week: the one for Market Street is 24,650 feet long, one and five-sixteenths inches in diameter, and weighs 72,000 pounds. The Castro Street cable is 22,000 feet in length. From ninety to two hundred and fifty days is the limit of the life of a cable in this city.

The Southern California Railway has one passenger, one freight and two switch engines running burning oil as a fuel successfully. The engine in the passenger service makes 190 miles and averages eighty stops daily. They have several engines which are about completed as oil burners, besides several others well under way which are to burn oil as fuel.

—The Stockton Car, Agricultural and Machine Works is shipping two harvesters to the Argentine Republic, the pioneer harvesters to enter that South American country. Five more of the machines will be constructed and sent to Argentine if these two prove successful, as they probably will. Two experts will be sent with the machines to properly start them to work.

—On the reported cut of the Washington lumber and shingle mills on the 1st inst., it is estimated that the sawmills of that State have an ordinary daily capacity of 7,500,000 feet of lumber, 15,000,000 shingles and 1,500,000 laths. The Tacoma mill made the largest cut: 257,000 feet of lumber and 90,000 laths in twelve hours, employing 210 men. The Port Blakeley mills were second. There are 280 mills in the State, about 250 being in operation.

At the annual meeting of the Canadian Pacific Railway Co., in Montreal, on the 3rd inst., the annual report showed the gross earnings to be $18,752,107, and working expenses $12,328,858, leaving net earnings $6,423,309. To pay interest on land bonds $2,112,729 had been taken from the reserve fund. The earnings per passenger per mile were 1.85 cents, and per ton of freight per mile 0.85 cents, against 1.69 and 0.87 cents in 1893. The Fraser river floods caused a loss of $550,000, and depression in business is responsible for the balance.

The cradle in which the big lumber raft is building at Stella, Wash., by Messrs. Robinson & Baines, is finished. Most of the piles of which the raft is to be constructed will be floated down the Cowlitz river. The steamer Alice Blanchard brought up from this city thirty tons of massive chains that will be used in binding the thousands of piles together, though it will take thirty additional tons of chains to complete the job. To avoid a disaster such as occurred to the raft towed out of the Columbia last fall, the builders are having a strong bulkhead put in each end of the raft. Instead of using a tug, this raft will be towed here by a large ocean steamer. The last raft, which went to pieces off the mouth of the Columbia, contained 10,000 piles, and the raft was over 400 feet in length. The builders and owners of the second raft propose to profit by their costly experiment.

—There is a growing tendency among manufacturers to use crude petroleum in place of coal as fuel. The use of oil is becoming common also in locomotives, and its general adaptability as fuel where coal has before been used renders it by reason of its greater cheapness and ease of handling a success as such an agency. Since the permanency of the oil wells of Los Angeles has been proven the railroads and manufactories of southern California have in many instances made a test of oil as a fuel, with the result that there is already a steady demand upon some of the wells for the entire output. There are at present in the neighborhood of 160 wells in Los Angeles capable of producing 2000 barrels of oil per day. The Santa Fe Company is now running four engines with good success with oil, and will change its entire locomotive equipment to oil-burners, probably within the next four months. The Los Angeles Terminal road is also running two oil-burning locomotives with good results, and has signified his intention of putting on more. The cost has been found to be about one-third as much as coal, and the use of oil is considered an unquestioned success.

—The Golden Cross Mill and Mining Co. are making extensive improvements. They now have forty stamps in operation, and will add sixty, the present number running till the additional sixty, now in process of construction by the Fulton Engineering and Ship-Building Works, are on the ground, where they will be placed back to back in the one building. The new machinery includes a compound Corliss engine, surface condensing. With them, fuel is an important item; the water used is pumped from the Colorado river, twelve miles distant, and piped to the mine from a reservoir. The new stamps are of steel, each 1000 lbs. weight. The Fulton Works are also building three other stamp mills, one of 30 stamps for the Silver Peak, Nevada, mine, another 30-stamp for the Whitlock, Mariposa Co., and a 10-stamp mill to be sent to Helena, Montana. They are also putting up a 100-ton refrigerating machine for Myer and Zobleman, brewers of Los Angeles.

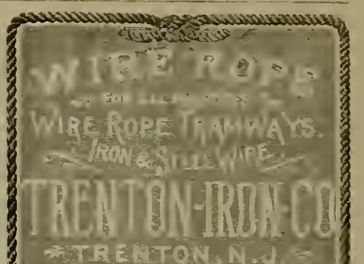
—The Durango, Flagstaff and San Diego railroad would cost, it is figured, $7,000,000, the following being the estimate of average cost per mile of single-track railroad:

Civil engineering and supervising	$ 110
Ten-foot cuts and fills	242
Track and tieing, laid	4,000
Bridging	317
Tunneling	15
Masonry	500
Piling	10
Rock cutting	400
Sidings	113
Telegraph	100
Buildings	500
Snow sheds, fences and plows	92
Total for tracks	$6,389
Total for equipment	2,000
Total for tracks and equipment	$8,389
Right of way, average	100
Total average cost per mile	$8,489

The contractors would do well, however, to double those estimates.

—The laying of a submarine cable between the United States and the Hawaiian Islands will be one of the vital questions to come before the 54th Congress. The recent refusal of the present House of Representatives to agree to the appropriation of $500,000 for the important enterprise was unfortunate. It is more than likely, however, that the next House will be more favorable to the enterprise, and the Senate will be as well disposed, at least, as the present body. But the President is understood to be opposed to any Government aid being granted the scheme, and consequently the probabilities are that no encouragement will be forthcoming during the present administration. Public sentiment may, however, become so strongly in favor of the enterprise that a two-thirds vote in both branches of Congress will be obtained to override a veto. That the enterprise is an important one and sure to be carried out in the near future is certain. The only question now is whether the project shall be hastened by the granting of governmental assistance, or whether it shall wait for the slower movement of private capital. It is estimated that the cost of a cable from this country to Hawaii would be $3,000,000. From Salinas Landing, in Monterey bay, to Honolulu is 2107 miles, and as the expense of making and laying a cable is placed at $1200 a mile, these two items would amount to $2,528,400. Allowing $471,600 for equipment, concessions and franchise, and the total cost would be $3,000,000. The British and Canadian Governments are willing to spend $7,000,000 in a Pacific cable. Why, therefore, is it unreasonable or bad policy for the United States to spend less than half that sum in establishing telegraphic communication with the key of the Pacific ocean?

—Most of the cross-ties on the coast lines of the Southern Pacific railroad are redwood. Some of the ties are made from pine and fir, treated with creosote or chloride of zinc to make it durable. As the supply of timber comes from widely separated points, and it is expensive bringing it to a central station to be treated with these preservatives, and then sending it to another place to be laid in the track, it was recently decided to make a portable apparatus which could be moved from place to place, thus reducing the expense of the preserving process by an amount equal to the saving of transportation effected. The apparatus consists of a train made up of a car equipped with two steam boilers, steam winch and other appliances; a car provided with a superheater, pumps and tanks; two cars, each carrying three wooden tanks for holding the preservative liquid, and two retorts, each six feet in diameter and 114 feet long, divided into two sections, each carried on two heavy car trucks. This train is hauled to a location such that the cost of moving the rough ties to it and the treated ties from it is reduced to a minimum. Then the retorts are connected with the other apparatus; the tracks are arranged so that the ties can be hauled in and out of the retorts by wire ropes, and the side tracks are laid so that the labor of handling the ties is as little as possible. The method of treatment with zinc chloride is comparatively simple. The charge of ties is run on metal trucks into the retort, and the heads or doors of the latter are bolted up. Next a preliminary vacuum is produced in the retort. It takes about ten minutes to produce this vacuum, and meanwhile the doors are bolted up tight. Live steam at about thirty pounds pressure is then let in, and is continued for about four hours and a half, about half an hour more being required to blow it off. During this steaming and blowing off the retorts are drained. For about an hour longer a second vacuum is maintained, and then the tank is filled with the solution of zinc chloride and put under pressure, which is maintained until the required amount of the solution has been absorbed. Finally the surplus fluid is drawn off, the doors opened and the charge hauled out. Another charge has been made ready in the meantime, and is immediately pulled into the same retort to undergo the same process. The total time of treatment averages about eight hours and a half, and the entire plant is capable of treating about 2500 ties in 24 hours. If the timber is to be creosoted the same plant is used, but the method of operation is different. The ties are first boiled in dead oil, and, after being dried, are then filled with the creosote by applying pressure. No vacuum is used, but the vapors given off during boiling are passed through a surface condenser, the outlet of the latter being left open to the air. The condenser enables the sap extracted to be measured, and also affords a means of recovering the lighter portions of the creosote carried over with the vaporized sap.



PUMPS!

SEALED PROPOSALS

Will be received by the CITY OF SACRAMENTO, CALIFORNIA, until MAY 1, 1895, for furnishing and constructing

HIGH DUTY PUMPING ENGINES

One (1) having a capacity of 5,000,000 gallons per twenty-four hours; the pump to be of the vertical triple expansion or cross-compound type.

The bid to include air pumps, valves, feed pumps, piping and all other appurtenances pertaining to a pumping plant, excepting boilers.

Steam-pipe connections must be made and furnished by contractor, also connections made and furnished to suction and mains.

The city to furnish concrete foundation for pump and build pump house.

Specifications may be obtained at the office of the City Clerk.

O. S. FLINT, City Clerk.

HEALD'S
Business College,
24 Post Street, - San Francisco.
FOR SEVENTY-FIVE DOLLARS
This College instructs in Shorthand, Type-Writing, Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.
A Department of Electrical Engineering
Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. G. S. HALEY, Sec.

VOLUME LXX. Number 17. SAN FRANCISCO, SATURDAY, APRIL 27, 1895. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

The Girard Water Wheel Company.

Among other present matters of local industry in this city is to be noted that of making Girard impulse water wheels, a branch of much importance from several points of view.

Americans, contrary to custom and tradition, have, almost without notice or participation, permitted the rise and development of impulse turbine wheels to go on increasing for forty years past in nearly all the countries of Europe, the only exception, and a very important one, being the development and manufacture of tangential wheels on this coast.

The impulse turbine was invented in this country long prior to its rise in Europe, but the inventor, in presenting his petition for a patent in the United States Patent Office in 1853 for an unfilled or impulse turbine water wheel, was informed that he had no standing in hydraulic practice, and his views were fallacious. The fact of his having constructed such wheels, and operated them under high efficiency, was not regarded as good evidence; but twenty years after, when Girard and others had demonstrated the value of the method, and firms in Europe were making and supplying such wheels, a patent was issued to Jearum Atkin, still living in Philadelphia, Pa.

The Fourneyron and Jonval wheels were introduced from France, and the American inward discharge turbines came up in many ingenious forms, but no wheels operating on the impulse system, except tangential wheels in California, and when the Niagara Commission came to consider water wheels for a head of 140 feet there were no plans furnished from this country that met with any consideration by the commission of engineers appointed for that purpose except the tender for tangential wheels prepared by the Pelton Water Wheel Co. of this city.

The reason of this is found in the fact that all over the Eastern slope, from the Rocky mountains to the Atlantic coast, and throughout the Mississippi valley, where so large a proportion of our national industries and population are situated, the streams are flat and the heads are low. Where this is not the case the volume of water is usually great, and the head is divided, in some cases, into three parts, so that turbine practice has all centered in the pressure or low-head type now made by not less than twenty firms and companies in this country.

The Girard or impulse water wheels, so called because M. Girard, of Paris, was most prominent in developing, explaining and designing such wheels, came to the front about 1860, being first made, but on plans now abandoned, at Zurich, in Switzerland, where, as on this coast, the high heads and pressures rendered the common turbine wheels impracticable.

Girard or impulse water wheels as distinguished from pressure turbines, and even from tangential or other impulse wheels, have peculiar features. They are capable

TABLE OF CONTENTS.

ILLUSTRATIONS.—The Girard Water Wheel, 257. The Lunkenheimer "Jewel" Grease Cup, 260. Plat of Mining Claims on the Galisteo River, New Mexico, 261.

EDITORIALS.—The Girard Water Wheel Company, 257. An Interesting Report; Wells, Fargo Cease Carrying Letters; Miscellaneous, 258.

SCIENTIFIC PROGRESS.—Interplanetary Communication; Improvements in Printing Machinery; An Auroral Search-Light; Experiments With Water, 264.

MECHANICAL PROGRESS.—Bell's Great Rival, 265.

ELECTRICAL PROGRESS.—Tesla's Oscillator; Reducing Electric Voltages, 264.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 266-67.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 270.

MISCELLANEOUS.—Concentrates; Personal, 259. Minas Prietas Camp, Sonora, Mexico; The Lunkenheimer "Jewel" Grease Cup; A New Use for the Air Caisson, 260. Santa Fe Placer Mining Co.; Rubies of Burmah, 261. Use of Petroleum to Prevent Boiler Incrustation; A Nevada Suggestion; New Books Received, 262. The Mineral Hydrocarbons, 263. Cost of Stopping a Train; A Novel Calculation, 264. A Machinist's Arm Filled With Wire; The Passing of the Horse; The Manufacture of Wild Men, 269. Notices of Recent Patents, 270 Coast Industrial Notes, 271

"COMPETITION is worse than war and a curse to the country," says a San Francisco clergyman. Gold mining is the one business in which there is no competition.

IT is the opinion of several able lawyers who have been consulted on the subject that the product of the mines is exempt from income tax. The output of a mine, being a product of real estate, cannot be taxed under that law, and mining companies need not pay taxes on their net profits. Of course this is not ex cathedra, but is the likely result.

LYING before us is an address recently delivered by Mr. M. P. Kennard, at a meeting of the Bank Presidents' Association of Boston. In it he speaks of the gold dollar as "our historical and inevitable single standard." Lying beside it is a silver dollar dated 1799. Around the edge is the imprint "One Hundred Cents, Standard or Unit." Either the old silver dollar or Mr. Kennard is mistaken. Probably Mr. K. thinks back or knows naught no further than 1873, and dates history from that as the great era in earthly chronology.

PATENT OFFICE RULES 65, 134 and 68, which were issued February 4th, in consequence of the decision of the courts in the Berliner telephone patent cases, went into effect last week, although they will not interfere with the practice of the office for six months yet. Heretofore an application for a patent whose claim was rejected could hold it in abeyance for two years before altering his specifications or appealing for a new hearing, in the meanwhile shutting out other patents by making slight changes. At the end of two more years an application could be kept still pending, thus prolonging the life of inventions much beyond the contemplation of the law. In the Berliner cases the patent was in the office for about fifteen years and was then granted to run for seventeen years. The courts declared this action illegal. The new rules require applications and appeals to be made within six months and direct the rejection of any claims that have been pending for five years unless the applicant can show cause why the case was not rapidly prosecuted.

A PLACER COUNTY MAN writes taking issue with an editorial statement made last week in which, where discussing the attitude of the *Record-Union* toward hydraulic mining, it was stated that that paper "had a right to be wrong." He says he doesn't see how any one has "a right to be wrong," and thinks such a thing as "a right to be wrong" is a paradox and that one "must be either right or wrong." Just so; but he has a choice of either, and free will in the choice. There was and is no intention to juggle with words. The idea is this: take the question of protection, or religion, or any other matter of personal belief that divides men and makes them take sides. A believes in protection: he is a firm adherent of that doctrine. B, his neighbor, as good a man, as honest of intention and as desirous of prosperity, firmly believes in free trade. Now protection and free trade are directly opposite. If A is right, B is wrong, and vice versa; yet A must not be blamed for implicit belief in protection, nor B for advocacy of free trade. Each has a right to his honest opinion. But they can't both be right, and the one who is wrong has as good right to be wrong as the other whose opinion is orthodox, and that right must be respected, and not unjustly interferred with. So with any public question. The *Record-Union* has a right to honestly believe that hydraulic mining is an invention of the devil and destructive to the commonwealth. Of course it is hard to see how any one in California outside of an insane asylum can honestly have such belief; it would be infinitely more to the credit of any one possessing such belief to go crazy, as that would argue the possession of brains; but, the *Record-Union* has that belief, and though wrong, has a right to so believe. This applies solely to the domain of opinion, creed, belief. The realm of facts and actions is quite another thing. When the *Record-Union* makes malicious and mendacious statements it transcends all right of opinion and deservedly elicits censure and reproof; but so far as honest beliefs and opinions are concerned, any one and every one "has a right to be wrong," which, after all, is only another way of saying that we are always willing to concede to others the same degree of consistency that we expect shall be accorded to ourselves.

Wells, Fargo Cease Carrying Letters.

Wells, Fargo & Co. are about to quit carrying letters in the United States. In view of the close personal relations of that company to the miners of this coast, that announcement is one of more than ordinary interest and awakens many reminiscences. For a generation, "Wells, Fargo" have been the old reliable. They always charged big prices, which looked very large sometimes, but whatever was in the front boot generally went through at any cost, and many a time they constituted the only link of mail communication. No matter how deep the snow or bad the road; no matter who went wrong or what happened, the treasure box and the mail generally got through, and the calling out of the addresses on the letters was the event of the day in many a mining town in every nook and corner of the Pacific States and Territories. For a generation the company was a better mail carrier and gave the miners better service than the United States Government. "Two bits" was steep for a letter as compared with three cents, the government charge, but the letter with "Wells, Fargo" on it went to its destination, while the government red tape often made costly delay in the delivery of a plain United States stamped envelope. For many years the price of a "Wells, Fargo envelope" has been five cents, which in many cases included a special delivery where received.

Next to the MINING AND SCIENTIFIC PRESS, the Wells, Fargo letter delivery was the oldest mining institution on this coast or in this country, and the cessation of its operations is in one sense like hearing of the dissolution of an old friend.

Wherever a mining camp was started, the concern had a business office as soon as the saloon, notary public, assay office and corral were in operation, and some of the smartest men on the coast have been local agents for the company, whose daily or tri-weekly mail delivery began when a stage commenced running to the new town. Its operations were on a very large scale; as far back as thirty years ago the company bought annually 2,000,000 three-cent stamped envelopes.

It is doubtful whether its mail delivery ever paid as a special branch of the business, but it put the company into such familiar touch with the miners; it was such a convenience, that it induced considerable business that otherwise it would never have secured.

It will buy no more envelopes from the Government, and when the stock now on hand is used up, the old familiar "Wells, Fargo envelope," "Paid on our coast lines" will be only a memory.

An Interesting Report.

From John Hays Hammond is received the report of the British South Africa Company, at the meeting held Jan. 18, '95. The scope of the concern is something tremendous, comprising the government and operations of an empire. The territory embraces the greater portion of that part of Africa between the 8th and 34th degrees of south latitude and the 17th and 35th degrees of west longitude; considerably over 1,000,000 square miles. It tells of peace and war; battles, marches, victories, treaties and results; of trade and gain; labor, language, religion, railways and capital; of mining, profit and prospective action. Part of it is a story of a conquest; part of it a narrative of a concession; more of it a history of a new East India Company; other parts tell of transcendent gain and great possibilities: all of it is as interesting as any current literature. The report shows that the company's opportunity is a great one, its actions imperial, its monopoly absolute, and its aims purely commercial. Where it could not coerce it temporized; where it could not buy it bribed; where it could not do otherwise it played lesser powers against each other and aggrandized all.

Any one of its many operations would be of itself a very large business transaction. Its capital runs into the millions; its power is practically limitless; petty questions of jurisdiction and privilege are overridden, and with true British dominance it makes profit of minor necessities.

The report is a complete compendium of information. It tells how to get to its ports from any part of the world: the route, cost, time, etc.; whether from Capetown to take rail or stage or mules; how to arrange for food and transportation; the necessary outfit, etc., then passes to a history of "The Matabele War," with a complete account of troops, campaigns, and tables of killed and wounded.

Civil administration and governmental affairs receive attention; legislative and judicial departments, "foreign relations," postal service and other governmental branches being given attention—the whole thing reading like a government report.

A complete history is given of the gold development of the country: a list of all the districts with particulars of the work done in each district, the depth of the shaft, the width of the ledge, the ore assay, the net result in pennyweights and grains, with minute details regarding a multitude of mining properties. A table is given of 69 distinct and separate companies and syndicates—sub-schemes in whose interests the main company participates—followed by Mr. Hammond's report on the mineral resources of Mashonaland and Matabeland, to which previous reference has been made.

The different newspapers—seven in number—are described; agriculture, the Jesuits, native races, surveys, rules and regulations for taking up mining claims, how land can be secured, licenses obtained, and a variety of other topics are discussed.

Some idea may be had of the extent of the company's "mining business" from the summary showing that from December, '93, to September, '94—nine months—there were 21,783 mining claims registered in the Matabeleland districts. One item in the company's balance sheet of accounts reads as follows:

"Matabele War Expenditure—defences in Mashonaland and for protection of life and property—war material, viz.: guns and ammunition, wagons, horses, oxen, tents and volunteer equipment—food and supplies used during the war and sundry expenses, £113,488 2s 11d." That was just a little incidental matter of half a million dollars expended, it being necessary to have peace even if they had to fight for it, on the same principle as in the old days at Pioche, Nev., when fighters were paid $20 a day by the Raymond and Ely and Hermes Companies to "stand off" rival claimants.

The whole thing is the chronicle of an empire, the opening chapters in the history of a new world where none but the daring venture and none but the strong survive, and is a straightforward and valuable account of the subjugation and development of a rich and savage region by the dominant race.

Concentrates.

THE mines around Butte, Montana, produce 8000 tons a day.

THE Gold Bluff mine near Downieville, Cal., is temporarily closed.

BUTTE, Montanu's, new directory cluims a population for that city of 51,579.

THE new directory of Helena, Montana, gives that city a population of 23,649.

THE Culumet und Hecla has declared a $5 per share dividend, payable Muy 10th.

THE iron in the tailings from the Pilot Bay smelter runs four to five per cent nickel.

CREEDE, Col., mine ownors have determined to pump out the mines and sink deeper.

THE Santa Rosa und Good Hope mines, Riverside Co., are about to give the cyanide process a trial.

T. H. TREVITRICK, a miner in the Hibernia mine near Burlington Montanu, was killed hy a cave lust week.

A. W. LYMAN, editor of the Helena *Independent*, is the only newspaper man in Montana who has to pay an income tax.

THE Reymert Mining Co. have bought the Mountain Chief mine in Humbug district, Yuvapai Co., Arizona, for $40,000.

SUPT. TAYLOR informs the Grass Vulley *Union* that a five-stamp mill will in a few weeks be placed on the Daisy Hill mine.

THE Daly, Utah, Company last Saturday shipped to San Francisco nineteen hars of silver bullion, containing over 22,000 ounces.

A Two weeks' run of a ten-stamp mill has netted the owners of the Royal Mining Company in Granite county, Montana 380 ounces of gold, worth $6,000.

THE machinery from the iron mine at Hotaling, Placer Co., was tukeu to Oukland this week, thus ending many high hopes. There is plenty good ore there.

HEAVY rains in Kern county have so contrasted the usual with the occasional as to interfere with the working of the dry washers at Red Rock and Goler.

THE Minnesotu Legislature has defeated an effort to establish a tax on the valuation of the mining properties instead of the output of the mines in that State.

A NEW miniug district is being opened thirty miles east of Walter station on the S. P. R. R., in Riverside county. The rock is reported to average $40, free gold.

THE steamer Lucy, used as a tug by the Treadwell Mining Company of Alaska, was wrecked on the 8th inst. off Port Houghton, Alaska. The crew was saved.

BINS are hcing received for pumping out the Granite Hill, Nevada Co., mine, preparatory to resuming work. An assessment of five cents per share has been levied.

THE Electric Power Co. are at work at Kernville, Cal., on their 60-ft. ditch which will discharge fourteen miles below with 230 feet fall, furnishing light nnd power.

THE Great Western Mining Company has heen formed in Spokane with $1,000,000 capitul stock to work the Great Western and Garden Chariot claims on Trail creek.

WILLIAM A. CLARK, of Butte, Montana, confirms the report that he will he the principal holder in the company that has purchased the brass plant of Wallace & Son, Ansonia, Conn.

WORK will soon commence on the erection of additional machinery at the Mammoth mine, Tombstone district, Arizona. When completed the mill will have a capacity of 300 tons per day.

ANN now South African analysts tell us that from thirteen 200-pound coal samples from the Witwatersrand an average of 3¼ dwts. of gold to the ton of coal has been obtained. What next!

ANTIMONY is abundant in different portions of this State. The only antimony smelting works in the United States are in San Francisco. Fifty per cent ore is worth about $50 per ton in San Francico.

THE Holy Terror property in the Black Hills, which South Dakota papers say has been turning out a daily net profit of $7000, has hecn shut down, hoth mill and mine. Litigation is the declared cause.

TRINITY county miners met at Weaverville last Sunday and subscribed a handsome sum to aid the California Miners' Association in their effort to protect mineral land from absorption by the railroad companies.

THE suit brought against Sheriff Gregory in the United States Circuit Court by the General Electric Company for $8000 on account of his detention of certain mining machinery at the Gover mine was dismissed.

SILVER is quoted at 67. The upward tendency of the white metal is very encouraging to the miners of Montana, but it must go to 80 cents an ounce before the average Montana silver mine can be worked at a profit.

COMSTOCKERS wherever scattered over the world will be interested to hear that the present proprietor of the International Hotel, Virginia, Nevada, has proposed to a Renoite to move the hotel to Reno. It orginally costs $280,000.

THE consideration in the Monte Cristo, Iron Horse and Enterprise deal, in the Rossland, B. C., district, was $65,000, of which ten per cent was paid down to the owners. Development work will proceed at once on the Iron Horse and Enterprise.

NEARLY one hundred square miles of placer ground has been secured hy New York men along Four Mile creek, Kautt Co., Colorado, who say they have $10,000,000 in sight. Forty miles of ditching and piping will be necessary to work the gulches.

ARTICLES have been filed at Spokane, Wash., to incorporate the Ohio and Idaho Mining Company, capital stock $50,000. Trustees—B. F. Lee of Lake Brady, Ohio; N. A. Clark, Cleveland, Ohio; W. I. Hinckley, A. B. Keeler and C. F. Lee of Spokane.

AS AN illustration of what new and proper mining methods will do, the Prescott *Courier* cites the instance of Lynx Creek, Arizona, where for twenty years nothing could be done with mines and the section had a veritable black eye. Now the entire district is a hive of industry, new machinery is constantly going in and $12 per ton ore is worked on a large scale with profit, while $30 concentrates are considered good. The day when only $100 ore could be handled has passed away.

THE Hecla Consolidated Mining Company of Glendale, Mont., paid last Thursday dividend No. 138, $15,000, being one per cent on the capital stock, making $60,000 paid in dividends this year, and a total paid by the company up to date of $2,070,000.

THERE is a water famine reported in Candelaria, and the residents are obliged to get their supply of that liquid from the locomotive tanks. The pipes that convey water from the White mountains to Candelaria burst last winter, and have not been repaired.

DURING the first three months of this year the Arizona copper Co. and the Detroit Copper Co., whose works are at Clifton and Morenci, Arizona, have shipped 4,265,835 pounds copper. The shipments for the last six months of '94 aggregated 8,688,307 pounds.

IN the Superior Court, this city, M. Thompson charges his partners, T. Clark and W. C. Stratton, with having unjustly withheld $78,000 due him under a partnership agreement in the Grand Victory mine, near Placerville, and wants a receiver appointed and the partnership dissolved.

IT is said that at one time after the breaking of the Utica dam at least seventy-five men were searching along the creek for gold. One person found a nugget worth $16, and many other chunks of the precious metal of considerable value were picked up along the course which the water traversed.

RETRENCHMENT has found its way into the constitutional convention of Utah. Salaries of State officers have been fixed at the following figures: Governor, $2000; Secretary of State, $2000; Auditor, $1500; Treasurer, $1000, Attorney-General, $1500; Superintendent of Public Instruction, $1500.

ACCORDING to a New York City paper Wall Street men have secured some auriferous property in North Cnrolina, where they hire natives to walk around and pick up gold nuggets. This is almost as good as the forming of an administrative alliance to secure U. S. bonds at less than par value.

DON MANUEL RIVEROLI, the discoverer of the copper mine at Santa Rosalia, has been arrested at Ensenada on orders from Governor Sangines, charged with the theft of a gold bar valued at $12,000, placed by the Ibarra Gold Mining Company in his charge, and which was stolen on the night of March 20.

THE Shasta County Development and Mining Company has incorporated; capital stock, $200,000. Object, to work and develop mines and mining properties in California and particularly in Shasta county. A. M. Graham, president; W. Foster, vice-president; J. A. Davis, secretary, and J. W. Fitzpatrick, treasurer.

F. X. PIMENTEL, F. F. Wetherbee, A. Miliken and S. Yriharren, with other parties, have organized a company in Durango, Mexico, to work the Jahrennio mine in Otaiz district. The company is heavily capitalized, and is credited with ability to immediate'y put half a million dollars into the enterprise.

THE Alaska Treadwell Mining Company has declared a quarterly dividend of 37½ cents per share, amounting to $75,000, payable next Monday. During March there was a profit of $20,455. The bullion shipped showed an average of $2.34 per ton of ore milled. The sulphurets yielded an average of $51.91 per ton treated.

IT has been known for years that the Contra Costa range carries mineral deposits—gold, silver and coal. Several prospects have been made in years past that were quite promising, hut the deposits have been small, excepting coal. F. Bohmer of Alameda has discovered hack of Fruitvale what he thinks is a rich silver mine.

THE American Mines Association, of Chicago, is attracting unpleasant notoriety. A capitalization of $25,000,000 is claimed and a dividend of sixty per cent on the total capital paid in. The assertion is made hy them that the Independence mine of Colorado has paid $5,800,000 dividends in two years. The Association's future seems to be behind it.

WILLIAMS & SONS, of Austin, Nev., have had several persons engaged of late grubbing up sagebrush, which they will burn as fuel in their flouring mill. Mr. Williams says he will determine which is the cheaper fuel, sagebrush or wood. In certain parts of the State sagehrush is used in quartz mills, and it is claimed that it is better than wood for heating purposes.

LAST Monday the Debris Commission granted permits to P. Phillips, W. and W. J. S. Bacchi and D. Croft of El Dorado Co., and J. J. and A. A. Hoffman of Placer Co. Authorizations to construct impounding dams for hydraulic mining were granted to J. Ward, W. McDonald and W. Henning & Co. of Placer Co., and W. F. Coe, J. C. Day and E. Russell of El Dorado Co.

WHILE working in a fifty-foot raise in the Monitor mine at Pioche, Nevada, last week, Frank Weidner got a dose of sulphuretted hydrogen gas and miraculously escaped death. After becoming senseless he fell on a plank in the top of the raise, where he hung for several hours until discovered by William Hammond and J. Bayle, who lowered him down to the tunnel level and brought him to the surface.

TEN YEARS ago all except the most sanguine miners would have told you that there were no gold mines around Ophir that would pay, but they did not at that time look forward to the improved methods of mining, milling and transportation, says the Ophir, Colorado, *Mail*. Ten years ago packing and milling cost $20; to-day the same ore is being mined, transported and milled at a cost of less than $5 per ton.

A FRENCH syndicate is thinking of paying $1,000,000 for the Mercur, Utah, mine. The monthly statement of the Mercur Company for March shows a net revenue from hullion sold of more than $49,000. That was for a total tonnage of ore of 4770 odd, making an average net return per ton of $10.50. Out of the amount the company paid a $25,000 dividend, all mining and milling expenses, officers' salaries, many necessary and usual expenses, and still had nearly $7000 surplus.

OMAHA and Denver smelters have introduced a device similar in effect to that used here for recovering minerals that pass away in smoke and fumes. It consists of a horizontal flue 1500 feet in length, exposing a surface for radiation and condensation of the heated gases of 54,000 square feet. Through this flue are drawn the fumes by means of a fan, the outer circumference of which revolves with considerable velocity, the fumes being forced into a spacious building, from which there is no means of escape except through a filter of textile fabric, the colorless gases passing through into a stack beyond, while the valuable soot or smoke condenses on the under side, from which it is collected from time to time, compressed into molds, and fed back again into the furnaces, where the valuable metals are extracted and separated.

SPEAKING of the late strike made in the Murchie mine, near Nevada City, the *Transcript* says: "Here is another instance of resuming work on a mine that had not been operated for ten years or longer. When the mine was being worked before, from fifty to eighty men were employed. After taking out all the best quartz that was in sight, the employes were discharged and later the mine was closed down completely. Since operations were resumed, considerable prospecting has been done, and as a result the company now have two fine ledges with an abundance of good quartz in sight to keep even a larger mill than they have running night and day for a long time.

THE history of the Londonderry mine, Coolgardie, West Australia, is interesting and instructive, if not edifying. Its original English purchasers sold it the other day, as it were, for $2,000,000. The directors of the new company met; amid much enthusiasm they were told that within sixty days five tons of gold would be mined from the company's property. The London mining paper from which this is concentrated has "Hear, hear," and "cheers" scattered through the statements. Meanwhile the directors had telegrams in their pockets telling them that "the reef was barren," and after they had unloaded, the news got out, and now the purchasers of stock say they have been swindled. It does look that way.

THE first shipment of gold bars from the new mill of Capt. J. R. De Lamar nt De Lamar, Nevada, reached Salt Lake last Saturday. There were $40,000 worth of gold in the shipment, the production of less than three weeks of operation. To transport the bullion from the De Lamar camp to Milford, on the Union Pacific, an overland trip of 170 miles, a Concord coach was provided and in it a globe safe containing the hars was deposited. Relays of fresh fours of horses had heen sent on ahead, and with the coach started four outriders armed with Winchesters and carrying an abundance of ammunition. The route was covered in about forty-eight hours. Hereafter shipments of bullion will be sent out about every week and the guards will be kept going along the road. The gold is consigned to the Wells, Fargo & Co. express.

THOS. MEIN, general manager of the Robinson Gold Mining Co., Witwatersrand, Transvaal, Z. A. R., sends us the 7th annual report of the company's accounts for the year ending December 31, 1894. During the year 50 new stamps were ordered added and seventy stamps were run from March 1st. The year's output of ore was 107,935 tons; from the mill was taken £402,330; from 2997 tons chlorinated concentrates was produced £57,981, and 70,525 tons tailings, treated by the cyanide process, yielded £65,397. The ore was wholly pyritic. During the year 234 Europeans and 1195 natives were employed; the latter were paid $3.62½ average wages per week, exclusive of food. The company's profit for the year was £346,628 13s 2d. The cost per foot of the 11,976 feet of development work was £2 19s 1d. The cost per ton of mining and milling the ore, exclusive of mine development, was £1 1s 8d. Fuel cost £3,706; water, £1,743. The report is an elahorate one, statistical and comparative with previous years, and interesting in every detail.

"THE appeal of the Cassel Gold Extraction Company, Limited, against the decision by which Justice Romer invalidated the MacArthur-Forrest patent," says a London technical journal, "has been dismissed by the Supreme Court. Lord Justice Smith's exhaustive judgment will probably not deter the plaintiffs from carrying their case to the House of Lords, as the interests involved are of considerable magnitude. It is noticeable, too, that the court arrived at their decision with great reluctance, inasmuch as the invalidation of the patent was not influenced hy any hut the most technical grounds. The patent has been upset simply because of a superfluous clause in the specification. In the words of the judge, 'had the first claim been omitted, we should not have been faced with the difficulty we are; . . . and for this reason, and for this alone, we must give judgment for the defendants.' It is undouhted that this decision involves much hardship, and brings into question one of the points with which the new Patent act is specially intended to deal."

THE Gold Dredging Company, a Chicago concern, controls three miles of placer ground on Crasshopper creek, adjoining Bannack, Montana, and is building a steam dredge to be placed in a scow, to dip the gravel and elevate it into a sluice hox, twenty-five feet nhove, in which the dirt will be sluiced. The power to he used is water power and electricity, including light, by means of which operations will go on hoth day and night. The water used for the generation of power has a full of 350 feet, which will give 250-horse power. The capacity of the dredge is estimated at 4000 cubic yards per day. Should the dirt yield but fifteen cents of gold per cubic yard, equivalent to one cent per pan, the profits will he great. S. S. Harper is manager. A force of forty-five men is employed at present, hut this will he increased to seventy-five as soon as dredging hegins, ahout May 15th. The amount of money expended hy the company so far is $98,000. The scow, which is now heing huilt at Bannack has a length of seventy-five feet and a width of thirty-six feet. Over 100,000 feet of lumher is heing used in its construction, and it is designed to carry sixty tons of machinery. The estimated dredge capacity seems high. A dredge that can handle one-fourth that much and do it right along will do very good work.

Personal.

T. J. BARBOUR, representing the Risdon Iron Works, has returned from southern California.

W. F. NEWELL, of the Selhy Smelting and Lead Co., is in Arizona, and will visit Mexico before his return.

F. N. SPEAR, manager Bradley Pulverizer Co., manufacturers of the Griffin mill, has returned from Boston.

MR. J. D. WEEKS, M. A., of Pittsburg, has heen elected president of the American Institute of Mining Engineers, in succession to Mr. John Fritz, of the Bethlehem Steel Company. The Institute has now a membership of something over 2200, including the most distinguished metallurgists and mining engineers in America and abroad.

Minas Prietas Camp, Sonora, Mexico.

In Sonora is a camp that is the Mecca of many a poor devil's pilgrimage, where men have headed for from every point of the compass. Every part of the world is represented there, and I dare say none of them ever made money any faster than right here.

I refer to the Minas Prietas camp, out of Torres, seventeen miles from the Sonora railroad.

The camp lays no pretentions to beauty. Streets there are none—just irregular rows of houses. The houses are adobe mostly, in various stages of dilapidation. Of stray dogs and burros and beggars there are more than you could shake a stick at. And the camp makes no pretentions at being a health resort. They have small pox all the time there, and pneumonia makes inroads among "the boys," and it is dusty and hot, and water is so scarce that the peddlers do not get into town with it. Yet there is no denying that Minas Prietas camp is attractive. There is ever the attraction of gold, and, where that is, hades itself would not deter. And the Minas Prietas is not nearly as bad as that. With its few drawhacks it is a good camp. There is always the music of three stamp mills playing golden chords, saying nothing of a Huntington plant and another twenty-stamps that will soon add their roar to that already there.

The inhabitants are such as may be expected in such a place—mostly natives, with Arizonans next, and lastly other foreigners. Good wages are earned and living is cheap. Pay runs from a peso and a quarter to $5 a day in gold. Living—that is, board—is fifty cents a day (American), with room rent in proportion to $25 to $50 a month for a house. Those with work appreciate having a good thing and hold on, while there is many a poor devil waiting for work. Let warning be taken now. They have extra labor enough in idle men waiting for jobs in Prietas to supply the places of all who may get sick, die or go away for the next year to come. I met an old man there who mistook me for a resident. He told me that he had walked all the way from the United States there, and wanted to know of the probahilities of his getting work. I saw him a day or two afterwards, and there was in the droop of his countenance a picture of utter despair. Of Tucsonites they have a dozen or so working in the mines and mills, with rather more from Nogales. Other parts of the Territory also come in for representation.

The sources of income of that camp are five or six of the best gold mines in the world. And the grand total of them is probably the very best gold camp in the whole world. When ore is so very good that they sack it in the mine, just to get it safely to the surface to mill; when the laborers will steal ore and gouge out their candles and fill them with the stuff; when dividends of $1900 a share—each share a twenty-fourth—are declared, as the result of a month's run of one mill, and that mill being of ten stamps, then some justification is found for the statement that therein is found probably the best gold camp in the world.

In the camp are seven mines, viz: The Verde, Creston, Prietas, Colorado, Amarilla, Santa Cruz and Grand Central. There is quite an assortment of colors—green, black, red and yellow. These mines are in all stages of development, from the Santa Cruz just being opened, to the Prietas which is no longer worked.

In Sonora they swear by the wealth of the Colorado mine. From this property more gold has probably been taken than from any other mine in Mexico. The output since the early '80s has been $20,000,000. Of this amount $11,000,000 has been dividends. Single bars of bullion valued at $40,000 have been shipped from the Colorado mill. The ore is in a twelve-foot vein, and varies from such a low grade as to be left in the mine, to the rich stuff which is full of "wire" gold that is worth a dollar or more a pound. The average value of the ore worked is about $30 a ton. The mine is down 650 feet. Five miles of work have been done in the Colorado. On the upper levels the paying ore is considerably stoped out. The richest ore was found in the second and third levels.

The mill is of thirty stamps, and its capacity is ninety tons a day. Not a moment is lost from one month's end to another at the mill. As continually as possible, days, nights, Sundays and holidays, the stamps chew up the ore. The property employs 150 men.

The Creston mine is a continuation of the Colorado. Here, too, the work is down 650 feet. The mine grows richer with depth. The ore mills an average of $14 a ton, and 100 tons a day are being worked, the results of which amounting to $1400, the expenses being $475, leaving a net profit of $925 per day. Considerable water—20,000 gallons daily—is encountered at the lower depths. On the 26th of last month the pumps got out of order and were flooded, requiring the placing of new ones in order to uncover the old pumps. Some rapid work had to be done.

The Crestou ore is worked at the old Minas Prietas mill. This mill is of forty stamps, working 100 tons a day. About 120 men are employed in mining and milling the Creston ore. Like the Colorado mine, the Creston is under the management of the heirs of Chamberlain & Price, Ohio people.

The Prietas is a mine of the past, the Colorado is a mine of the present and the Amarilla is a mine of the future. This last-named property is the talk of half of Sonora. One old Mexican recently described its output as being "oro puro." While it is hardly pure ore, it has free gold in quantities enough to justify its being prized as a very big thing. For the month of February the mine's dividends were $1900 a share, each share being a twenty-fourth. The mine pays dividends while a mill is being built, and the ore is being hauled by ten-mule teams to a neighboring mill—the Grand Central. So rich is the ore that guards follow the wagons from the mine to the mill, to see that none of it is stolen; it is very free milling, and is said to run from $200 to $600 a ton. The width of the ledge is from five to twenty-five feet and grows wider and richer as depth is attained; its dip is about 80°. There are three shafts on the property, one being down 165 feet; and a contract has been let for sinking a new shaft 1000 feet. When this is done the Amarilla will probably drain all of the water of the district to itself, and thereby will solve the vexed water question—for that management.

The Amarilla was a blind ledge, parallel to the Colorado, and was located in August, 1893, by Pedro Negro, an Italian. The purchaser was Howell Hines, superintendent of the Colorado-Creston; he had twenty-two shares, John Hines (his brother) one share, and Robert Stein one share. An engineer in the Colorado had a chance to get a partnership in the property, to the extent of two or three shares, but he had no faith in it. The price paid for the mine was $50,000. It is said that $2,000,000 was refused recently. A twenty-stamp mill, with amalgamators, pans and settlers, is now being erected; its sides and roof are to be covered with corrugated iron roofing instead of lumber sheeting. The mill is not over the shaft, there being a bucket-line of twenty buckets from the shaft to the ore bins. About 100 miners are employed in the Amarilla.

The Verde is another rich property, running parallel to the other ledges. The ledge is six feet wide and the ore runs $300 to $400 a ton. So rich is the ore that it is sacked to be brought from the mine to the mill. When I was there last week the mill was shut down while the pumps at the Creston were being gotten in order.

The Verde is owned as follows: Howell Hines, twenty-one shares; Superintendent McGregor, one share; John Hines, one share; Mr. Goodwin, one share.

The mill is a Huntington with Frue vanners, and works about eighteen tons a day.

The Grand Central mine is another rich property, owned by a Mr. Seymour, of England, who came to the camp after the Cerro Blanco fiasco. About a mile of work has been done in the mine. The lowest grade ore is said to be $12 per ton. The management is said to be in close straits for water, having been shut down, so far as the Grand Central ore is concerned, for eight months. The mill of ten stamps is now rented to the Amarilla management, who get their own water. Mr. Seymour is "between the devil and the deep sea," as to selling the mine or developing water.

The Minas Prietas is the pioneer mine of the district, worked down 500 or 600 feet, at which time fire burned out the timbering. It belongs to New York capital. There is talk of renewing the work there.

The Santa Cruz is a newly opened ledge near the Amarilla, and will be worked in connection with that mill.

The whole district is No. 1. The mines are worked with American foremen and Mexican and Yaqui labor. The mine laborers lose no opportunity to appropriate the "wire" gold to their own use. The hollowing out of their candles and concealing gold therein I have already mentioned. Another trick is to have a bundle of cigarettes. The cigarettes are filled with wire gold. A red handkerchief full of rich stuff has been sent out with a car of waste, in the hope that, the waste being also red, it would not be noticed. The handkerchief was espied on the dump by the keen eyes of Howell Hines, and investigation brought to light several hundred dollars worth of gold.

The miners work almost naked, the lower levels being very warm, so they have little chance to smuggle out gold in their clothing.

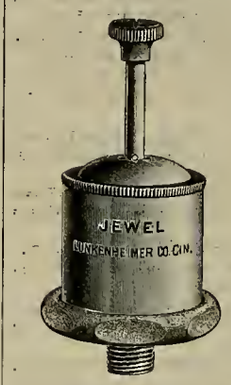
The settlements are divided into two towns, Colorado and Minas Prietas. The railway station is seventeen miles away, and seven stages run between the two points. Sometimes, even with that number of conveyances, passengers are left behind. P. H.

The bottom of the Atlantic forms a sort of terrace along the continent, sloping gradually for several miles, then suddenly descending to a far greater depth. In general, about 100 miles from the shore there is a depth of 100 fathoms, but in ten miles the depth exceeds 1000 fathoms.

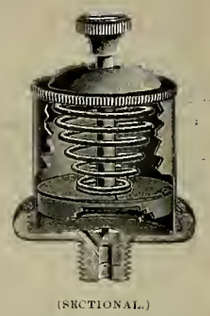
Brazil is a Portuguese word, signifying "a live coal." It was given in allusion to the abundance of red dye wood found in the forests.

The Lunkenheimer "Jewel" Grease Cup.

The engravings below represent the latest achievement in the grease cup line, made by the Lunkenheimer Company of Cincinnati, Ohio, with branch offices at No. 51 John St., New York, and No. 35 Great Dover St., London. It has been designed to meet the demand for a simple and inexpensive automatic grease cup and to take the place of iron cups, being stronger and lighter in weight. The "Jewel" is admirably adapted for shafting, loose pulleys, friction clutches and many other places. The base is of cast brass, while the top is of tubing and spun brass. It is of brass throughout, has a leather-packed plunger and is provided with a feed-regulating screw in the base of cup, which will admit of perfect regulation of feed. The makers claim this cup to be far superior to iron cups and is offered at prices that defy competition.



EXTERIOR VIEW WITH PLUNGER DRAWN TO TOP OF CUP.



(SECTIONAL.)

CUPS EMPTY WITH PLUNGER AT BOTTOM.

The working of the cup is as follows: When empty and plunger is at bottom of cup, unscrew and take off the reservoir; then lift the plunger to top of same and secure it in this position by means of the lock arrangement, then fill the reservoir with grease, screw it back into its base, release the spring lock so as to put the pressure on grease and the cup again feeds automatically until empty. The feed-regulating screw in base of cup permits adjustment of the opening through the shank of cup to suit any kind of grease.

This cup is claimed to be the simplest, most efficient and lowest priced automatic grease cup on the market. This company, besides making the above, offers several other styles of grease cups for various purposes, as follows: the "Ideal," "Marine," "Tiger," and "Ohio" grease cups. Full particulars can be had by addressing the company. Catalogues, circulars, etc., upon request.

A New Use for the Air Caisson.

Some months ago the Santa Fe Placer Mining Company, of Kansas City, Mo., desired to thoroughly test for gold the material forming the bed of the Galisteo river near Santa Fe, New Mexico, and as the material was strongly impregnated with a subflow of water from top to bottom, the usual method of cribs and pumps was not attempted, and the idea of using an air caisson was conceived as the only *certain* way by which bedrock could be reached and the material given a thorough test.

In pursuance of this plan, an air caisson was constructed of one-fourth-inch steel, cylindrical in form and twenty-nine feet long, in two sections for convenience in handling. The lower section contained the air chambers and was divided into two compartments by three-sixteenth-inch steel heads fitted with air locks 18x22 inches. The lower lock was placed eight feet from the bottom and upper lock six feet above the lower one. The upper section was a shell and was fastened to the lower part by 3x3 angle iron and bolts, and all fitted with air and blow-out pipes, valves, etc.

The caisson was built with straight sides, *i. e.*, without batter, so that it could be withdrawn from the ground and again used.

Equipped with the necessary power, air compressor, derricks, etc., the company began the prospecting work on their property, which consists of about four miles of the river bed, on Nov. 20, 1894, and finished the work about ten weeks later.

The caisson proved eminently successful in every way, disclosing the material from top to bedrock, from which cube-foot samples were taken at each foot of depth reached and given a careful analysis. The remaining material was blown or hoisted out, as its nature required, and was sluiced by the usual methods. From five to fifteen pounds air pressure was maintained, according to the depth reached and the compactness of the material being penetrated. At a depth of twenty-eight feet the caisson required a sinking weight of about 50,000 pounds to overcome the friction and lifting power of the air forced into it. The material penetrated was sand, gravel and stones, with an occasional thin streak of adobe.

Some uncertainty was felt as to the possibility of

pulling the caisson out after it was sunk its length, but this was removed when the trial was made. With slings about it connected with a steam hoist and an air pressure pumped into it, after letting in one or two feet of water to act as a cushion, of twenty pounds to the square inch, it came up "too nice for anything," and the plant moved to another location for a similar test.

It might be proper to add that the gold disclosed by the caisson was as satisfactory as the workings of the caisson, and the company is now receiving bids for a steam dredge, centrifugal pumps, etc., with which to secure their find. A conservative estimate of the coarse gold, based on the disclosures made by the caisson, is six and one-half millions of dollars' worth of gold in the property of the company.

As this is the first instance, to my knowledge, where the air caisson has been applied to this use or has been constructed with the intention of pulling it up bodily to be again used, the experience is mentioned in the hope that it may be of value to others having the same problem, and I shall be pleased to answer any inquiries as to cost and details at any time.

F. E. NETTLETON,
Kansas City, Mo. General Manager.

Santa Fe Placer Mining Co.

The accompanying map shows the property of the Santa Fe Placer Mining Co., New Mexico.

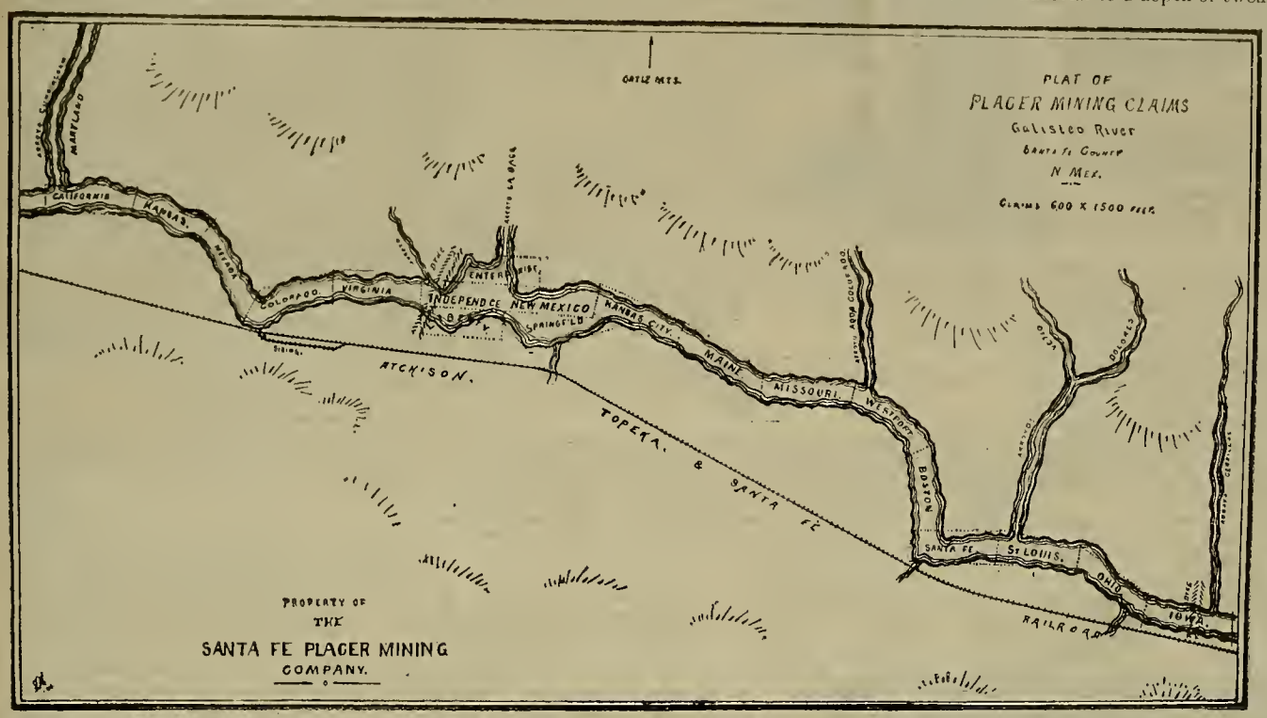
The property of this association consists of some four miles of the bed of the Galisteo river, comprising twenty placer mining claims of twenty acres each, each claim being 600 feet wide by 1500 feet in length, situated in Santa Fe county, New Mexico, about twenty-five miles from Santa Fe, on the line of the Atchison, Topeka and Santa Fe Railroad, the nearest station being two miles from the lower claims.

The Galisteo river flows at the northern base of the Ortiz mountain, which covers an area of about 100 square miles. Immediately under both the northern and southern slopes of the mountain are deposits of placer gold, which have been worked since 1711 A. D. by the Spaniards, and by Aztecs prior to that time.

All the gold in these deposits has been eroded from this mountain. The claims of the association have been located to embrace the mouths of the principal arroyos or gulches which lead from the "Old Placers" on the north side, so that the gold wash is concentrated in this property, from which there is no exit except down the river; and because of the semi-suspended condition of the material in the water of the river, also the specific gravity of gold, it is assumed that the greatest deposits would be found near the bedrock of the river. The preliminary work just completed goes to show the correctness of this theory, and that the sub-flow of the water in the river extends from the surface to bedrock.

The preliminary work also demonstrates there are no large boulders at the bottom of the river. The material to a depth of twenty feet can be taken out by means of a centrifugal pump at an alleged cost of not to exceed five cents per cubic yard.

The association has been incorporated under the laws of New Mexico, with a capital stock of $100,000.



Rubies of Burmah.

A large quantity of the world's supply of rubies comes from the Burmah mines, which have been actively worked since the annexation of Burmah by the British Government. The ruby district is about twenty-six miles long and twelve broad and lies at elevations varying from 4000 to 5000 feet above the sea level. Some of the mines have been worked by the natives from very remote periods—in fact, old workings are found over an area of sixty-six square miles. It is in the lower clay beds of the river alluvia, and in similar deposits formed in gullies in the hill-wash, that the rubies, spinels and other gems are found. In the alluvia, square pits from two to nine feet across, ingeniously timbered with bamboo, are sunk to the ruby earth, which is drawn up by bamboo baskets. In the hill-wash, long open trenches are carried from the sides of a gully. Regular mines are opened in some places; in others the limestone is quarried.

JAPAN could, if obliged to, put 500,000 trained soldiers in the field. She probably did not employ over 100,000 in the late war.

Continued from page 257.

of regulation as to speed and capacity without loss of water, and will operate with the same efficiency under great changes of load and quantity of water applied and are capable of receiving a large volume of water on a small wheel, so the speed of revolution can be made to suit any case without gearing. The issues or nozzles can be of any number, from one to a dozen or more, and in regulating, these issues are entirely cut out, or their area changed, so that all the water applied on the wheel meets the vanes at full head and pressure. Throttling the water supply and diminishing the pressure is not necessary, this being an important point, for the speed of a water wheel being as the head or pressure, throttling the water with any kind of a valve in the supply pipe lowers the pressure, changes the relative velocity of the wheel and water, and efficiency rapidly falls off.

The water is applied on the interior of the wheels, and passes out radially through the rim assisted by centrifugal force, and falls clear of the running elements. The efficiency need not be a matter of discussion, as any competent engineer capable of analyzing the nature of forces, and with knowledge of hydraulics, can easily compute the efficiency of water applied on this method. It is claimed by the makers that no other type of water wheels can give out more power with a given amouut of water under heads from 20 to 2000 feet. The diagram, Fig. 2, shows the manner of applying the water, and the curves indicate its course through the wheels.

The automatic governors employed by the Girard Water Wheel Company to control the regulating apparatus are much more complete than any that have been applied in Europe. They operate on the inertia system—not by both momentum and inertia, as in the case of steam-engine governors, but by the inertia of the driven machinery communicated through the driving pulley and opposed by centrifugal weights, so the whole power of the wheel is communicated through the governor. This is au intricate matter not easy to explain without drawings, and difficult even then. The most marked feature is that the governor will, at its neutral or normal position, where common governors have but little effect, exert full force either way for minute changes.

For low heads, from twenty to fifty feet, the water can be applied all around the wheels if required, because one nozzle or issue does not interfere with another, and they can be placed nearly together, being separated by thin guide vanes only.

M. Guyelin sends elevations of the late plant designed by him and now in use at Niagara Falls under a head of 140 feet. The Fourneyron type of wheels for the main plant, that of the Niagara Falls Company, were made from designs supplied by Messrs. Faesch & Piccard, of Geneva, Switzerland. The Guyelin-Jonval wheels were contracted for subsequently, but are the first at work, and have been running for nearly a year past.

The Jonval, as a pressure turbine, in which class it is supposed to helong, is readily adapted to operate as an impulse or unfilled wheel. The drawings received from M. Guyelin render it difficult to determine how far his plans involve impulsive action, hut the general design appears superior to that of Messrs. Faesch & Piccard. Since Atkins' invention, forty-two years ago, these new wheels at Niagara Falls are almost the first examples in impulse waterwheel practice in this country, except the tangential type made on this coast, meutioned above.

It is of further credit to San Francisco that the subject is taken up here in a manner that indicates thoroughness, and with improvements that adapt the wheels for use on this coast—that is, with economy of water and good regulation under high heads and small volumes.

The drawings herewith, Figures 1 to 6, especially the diagram Fig. 2, will explain the nature of the wheels and the modifications proposed by the Girard Water Wheel Company, who are now building wheels of this kind at their works, 34 and 36 Main street, San Francisco, Cal.

Use of Petroleum to Prevent Boiler Incrustation.

Although petroleum was used for this purpose as early as 1875, there has been until recently great division of opinion upon the subject. Roman Zalocieckl concludes that the negative results hitherto attained with petroleum are due solely to lack of practical experience in using it. Either was the quantity employed too large or too small or the oil not sufficiently refined. Too much petroleum will cause an incrustation upon the lower wall of the boiler next to the fire, that easily leads to a burning through; while a poorly refined product, because of the acid it contains, attacks the rivets so that they become thinner. Regulation of the flow of the petroleum is importaut, that a constant quantity may always be in the boiler. Ahout a thousandth part of the volume of feed water usually suffices for the amount of petroleum, which may be allowed to flow in with the water either continuously or periodically. For this purpose it is best to have an automatic arrangement to regulate the flow. The effect of the petroleum is to impregnate the solid particles in the water so that they circulate around without settling upon the bottom, and generally do not form a sediment that adheres to the wall, hut merely a scum, which must be removed from time to time.—*Bericht des galizischen Landespetroleumvereins.*

Publications Received.

"*Speech of Hon. S. M. White of California on the Maritime Canal Company of Nicaragua,*" recently delivered in the U. S. Senate, devoted to demonstrating the practicahility and commercial necessity of building that waterway under American auspices. One of the most interesting parts of Senator White's address is the evidence he adduces regarding the value of creosoted timber in preserving piles from the ravages of the teredo.

"*Catalogue of the Michigan Mining School,*" published by the Mining School, located at Houghton, Mich., a compendium of information regarding that institution; 214 pages descriptive of every department of one of the foremost mining schools in the country. In the reading room of this institution are to be found 224 of the leading scientific and educational publications of tbe world.

"*Sketches of Wonderland,*" an illustrated pamphlet dcscriptive of the country traversed hy the Northern Pacific Railroad. Smalley and others have had so much ahout tbat region that the first idea is the handsome appearing hrochure is only a re-hash of what has formerly appeared, hut examination shows this to be original throughout, superbly illustrated and fairly stated. What is new is good, and much that is good is new. The company has finally and sensihly quit trying to dub Washington's greatest mountain "Tacoma," and taken to calling it Ranier. An ascent of that famous peak is finely described, and Yellowstone Park for the one hundredth time is given great prominence. The book is the handsomest and most deserving tbing seen in railroad literature for the past two years, and any one caring to read it can get a copy by sending tbree two-cent stamps to Chas. S. Fee, Gen. Pass. and Ticket Ag't N. P. R. R., St. Paul, Minn.

"*Elasticity a Mode of Motion, Being a Popular Description of a New and Important Discovery in Science,*" is the title of a work of 61 pages by Roh't Stevenson, C. E., M. E., etc., who alleges therein his cognizance of the true cause of gravitation, and announces his new kinetic theory relative thereto. The work is finely printed on excellent paper and is for sale by the San Francisco News Co.; price 50 cents.

A Nevada Suggestion.

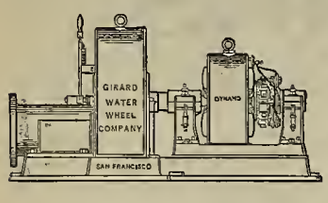
The Independence mine, Cripple Creek, Colorado, declared profits in 1895 as follows:

January	$159,000
February	105,000
March	130,000

Making for the first quarter in 1895, $364,000. The number of men employed is 28, four of whom are stoping. A simple calculatiou will show that it costs less than 60 cents to produce an ounce of gold from this mine. If the cheapness of production, as urged by the opponents of silver, from such mines as the Mollie Gibson and the Granite Mountain, is a reason for the demonetization of silver, why not demonetize gold ?—White Pine News.

TEMPERING in a bath of lead is employed especially for the very hard steels that crack if water or oil be used for that purpose. The process consists in heating the plate to be tempered uniformly to the temperature of 900° to 1000° C., and then plunging it in a hath of melted lead at 350° to 400°. The plate is left in the hath till its temperature is the same as that of the lead, perhaps 400°. Applied to the soft steels this process does not increase their hardness, but it improves them.

American Girard Water Wheel.



Adaptable to all heads between 30 feet and 2000 feet, particularly where economy in the use of water and fine regulation are desired, as, for instance, the operation of electric dynamos.

Girard Water Wheel Co.,

34 MAIN STREET, - - SAN FRANCISCO, CAL., U. S. A.

NEW SEAMLESS TUBE OLD LAPPED TUBE

SEAMLESS TUBE HOSE.

Our patented Seamless Tuhe Hose is the most valuahle improvement made in hose in recent years. In the old way the tuhe is formed from a sheet of ruhher, fifty feet long, of a width to encircle the hose pole, lapped and cemented (many times imperfectly), and the water gets through to the canvas and rots it, and the hose bursts. Our seamless tube is run the same as lead pipe is made and is free from defects. This process is employed in all sizes from one-half inch to the largest fire hose. Buy these goods and you are sure to get the worth of your money.

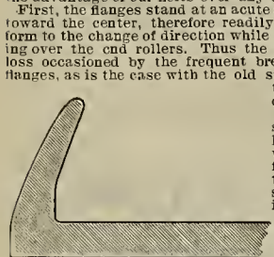
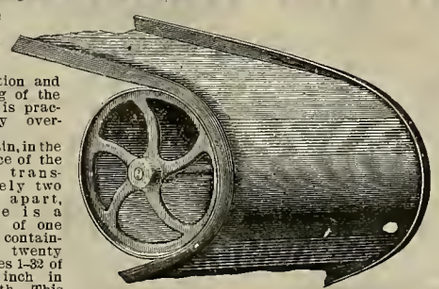
Blasdel Improved Concentrating Belt.

We keep in stock helts suitahle for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our helts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.





Again, in the surface of the helt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from hanking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a helt with an entirely smooth surface.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXVI

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1891, by Henry G. Hanks, F. G. S.

Sulphuretted hydrogen, known also as hydrosulphuric acid, may be recognized by its peculiar smell, like that of rotten eggs or bilge water. It is composed of the elements sulphur and hydrogen, as its name indicates, combined in chemical equivalents; its symbol is HS, and its atomic weight 17 by the old system, which is doubled in the new. Water at ordinary temperatures dissolves or absorbs three times its volume of this gas. The odor of the so-called "sulphur water" found in many parts of California is due to the presence of hydrosulphuric acid gas. In some localities it escapes in large quantities from the ground. The most noted in the State are the mud volcanoes or "salses" in the Colorado desert, San Diego county, the Sulphur Bank, Lake county; and Sulphur creek, Colusa county. Sulphur springs are common and numerous in different parts of the State.

Sulphur in active solfataras is supposed to result from the decomposition of two gases, hydrosulphuric acid (HS) and sulphurous acid (SO_2), thus ($2HS + SO_2 = 2HO + 3S$), or by the oxidation of hydrosulphuric acid gas, thus ($HS + O = HO + S$). The oxygen may be derived from decomposed water or by some secondary reaction. Both these gases are abundant at the mud volcanoes, at the Sulphur Bank and at Sulphur creek. Solfataric heat is not sufficient to sublime sulphur and it would seem that it must result from decomposition. The deposition of sulphur from hot alkaline sulphides at Sulphur creek may be seen at any time; all the tanks, pipes, conduits and bath tubs are whitened by a deposit of finely divided sulphur.

While sulphurous acid gas does sometimes leave the earth as such, its occurrence is very rare as compared with the other gases mentioned. It has so strong an affinity for hydrogen that it generally combines with it and becomes sulphuretted hydrogen. Sulphurous acid gas is, with but little doubt, the result of the decomposition of pyrites, a very ubiquitous and common mineral, so subject to change that if a sample after washing is simply dried on a water bath, the gas is distinctly evolved, and may be distinguished by its odor, that of burning sulphur.

Daubeny refers to the production of sulphur in the valley of "Vado Mortale," near Vesuvius, thus: "A vast accumulation of sulphur takes place in this valley, owing doubtless to the sulphuretted hydrogen, which is emitted in such quantities that it has been proposed to collect it for commerce, and petroleum has been likewise met with intermixed with the former combustible." (History of Active and Extinct Volcanoes, fol. 144.)

Sulphur is largely produced in Italy, mostly in Sicily, and, if I am not mistaken, it is all from solfataric deposits. The following, compiled from American and Italian statistics, will convey an idea of the magnitude of this industry:

YEARS.	Total production of Italy, tons.	Imported into the U. S., tons.
1881	323,151	102,771
1882	394,093	92,944
1883	391,689	92,861
1884	367,712	No returns.
1885	377,194	94,370
1886	326,657	112,283

At the Sulphur Bank quicksilver mine, in Lake county, sulphur was somewhat largely refined from the crude natural mineral during the years 1865 to 1868 inclusive. The total production was 941 tons, all of which, it is reasonable to suppose, was set free from hydrosulphuric acid gas in the manner described.

Carburetted hydrogen is a gas of quite a different nature from those above described. It is a true hydrocarbon, the elements carbon and hydrogen being combined in proportions to form a compound which is gaseous at ordinary temperatures. It is very light and inflammable; as soon as it is set free from the earth it rises, if not above the atmosphere, at least to an altitude near that position, and quite beyond our future observation. Its chemistry, physical properties, and history in California will be specially considered elsewhere.

California localities are numerous, but the quantity is small although important. That there has not been a gas excitement worthy of the name and that there are no great manufacturing centers here, depending on natural gas for fuel, is the best evidence that California gas emanations, whatever they may become in the future, are not to be compared with those of the Eastern States.

Natural inflammable gas is known to escape from the earth in the following counties: it may do so in others: 1, Alameda; 2, Amador; 3, Butte; 4, Colusa; 5, Contra Costa; 6, Fresno; 7, Humboldt; 8, Kern; 9, Lake; 10, Los Angeles; 11, Mendocino; 12, Merced; 13, Monterey; 14, Orange; 15, Sacramento; 16, San Joaquin; 17, San Luis Obispo; 18, San Mateo; 19, Santa Barbara; 20, Santa Clara; 21, Santa Cruz; 22, Sonoma; 23, Ventura; 24, Yuba; 25, Placer.

In describing the gas springs in the various counties, with the exception of Colusa, Contra Costa, Lake and San Joaquin, which I have personally examined, I have relied on newspaper accounts.

(To be continued.)

WANTED!

$2500—Wanted, a competent and honest quartz mill man, with above sum, to take half interest in custom quartz mill, permanent and desirable.

$5000—Wanted, a competent and honest quartz mill man (assayer preferred) to take interest in a custom quartz mill, chlorination works and a group of developed mines.

Both of these investments are safe and desirable, and invite investigation. For particulars, address

G. B. ROBERTSON, Attorney-at-Law,
YREKA, CAL.

PUMPS!

SEALED PROPOSALS

Will be received by the CITY OF SACRAMENTO, CALIFORNIA, until MAY 1, 1895, for furnishing and constructing

HIGH DUTY PUMPING ENGINES,

One (1) having a capacity of 5,000,000 gallons per twenty-four hours; the pump to be of the vertical triple expansion or cross-compound type.

The bid to include air pumps, valves, feed pumps, piping and all other appurtenances pertaining to a pumping plant, excepting boilers.

Steam-pipe connections must be made and furnished by contractor, also connections made and furnished to suction and mains.

The city to furnish concrete foundation for pump and build pump house.

Specifications may be obtained at the office of the City Clerk.

O. S. FLINT, City Clerk.

HEALD'S
Business College,

Scientific Progress.

Interplanetary Communication.

Scientists who have beeu wedded to the theory that we shall one day be able to communicate between one planet and another, must regard the present trend of speculation and knowledge in the world of science with some complacency. It was announced some time ago that Mr. Lowell, the astronomer who conducted a series of investigations at Flagstaff, Arizona, observatory, on the canals and other features of Mars, had become convinced that the planet is inhabited by intelligent beings. His explanation of the "oases" connecting the "canals" is that they are fertile spots of an oval or circular shape, usually sbout 100 or 150 miles in diameter, and of green so dark that it is quite distinct in the telescope at the distance of 40,000,000 miles. He states that it changes with the season like that of the foliage of the earth. Following on these speculations, now comes Tesla's marvelous discovery that not only has the earth an electrical charge of its own, but that this charge can be demonstrated and utilized. This means that we have now at haud an inexhaustible source of power of which the whole world can avail itself; in other words, that every bit of machinery in operation on this earth can be actuated by electricity drawn from the earth itself. This discovery also opens out the way for transmitting intelligence all over the world without wires. But to astronomers the most iuteresting bearing of these new facts is that they render possible a system of communicating with the inhabitants of other worlds. If this earth has an electrical charge, and all the other heavenly bodies have the same, as undoubtedly they have, the first great difficulty in the problem of interplanetary communication has been overcome, and we have found a means of sending messages across chasms of space.

Improvements in Printing Machinery.

The American Sunday newspaper is the wonder of the Old World, and it would almost seem as if the enormous editions issued by some offices for the delectation of their Sunday readers had exhausted the possibilities of modern newspaper production. That such, however, is not the case, is evident from the constant succession of patents being taken out for improvement in newspaper printing machinery. The ingenuity and complication of some of these machines is remarkable. The specification of a machine for feeding sheets of paper to a printing press, occupied nearly eight pages of a recent number of the Patent Office Gazette, and contained not less than sixty-nine distinct claims.

An Auroral Search-Light.

An indication of the estimation in which the search-light is now held as a medium for the projection of light to distant points is recorded from England. An electrical journal says it is significant of the spread of electric apparatus, which were a few years ago regarded rather as curiosities, that the recent fine display of the Aurora Borealis in the uorth of England was by many people put down to the now more familiar beams of a search-light. It was only when, on comparing notes, it was found that the display had been seen in far distant places out of the range of any possible projector, that this very practical explanation was abandoned.

An Experiment with Water.

Take a pound of water, the temperature of which is 80° C. and mix it with a pound of water at 0°, or freezing point. The mixture will make two pounds of water, the temperature of which is 40° C.

Now take another pound of water at 80° C. and mix with it a pound of crushed ice—that is, ice crystals at 0° C., the same temperature as the cold water in the first mixture—and the result is that we have two pounds of water at freezing point.

In both cases the weight of matter at 0° C. introduced into the warm water was the same; but before the ice crystals could assume a liquid condition, they had to absorb a certain amount of heat. The heat was drawn from the warm water, and consequently reduced its temperature, but it did not raise the temperature of the ice. It simply acted as energy in enabling the ice to become liquid, and remained in that liquid in the form of latent heat, to be given up again as soon as the water resumed a crystalline form.—London Knowledge.

Cost of Stopping a Train.

A locomotive engineer talking on the above subject says: "It is not generally kuown what loss of power is involved in the starting and stopping of an ordinary train of cars. There is required about twice as much power to stop a train as to start one, the loss of power depending upon the momentum. A train going at the rate of sixty miles an hour can, by means of the Westinghouse air brake, be stopped within 120 yards from the first application of the brake. Now, enough power is lost to carry this same train fifteen miles over a plane surface. First, there is the momeutum acquired by the traiu flying at this remarkable rate of speed, theu the loss of steam in applying the brakes, aud lastly but not least, the extra amount of coal to compensate for all these losses. By computation I have ascertained that every complete stop involves a cost of $1.17."

A Novel Calculation.

According to M. Eiffel, the cost of lives of any great engineeriug work can be estimated, at least as accurately as the cost in money. "It has been found," he says, "by statistical observation that in engineeriug enterprises one man is killed for every 1,000,000 francs spent on the work. If you have to build a bridge at a cost of 100,000,000 francs, you know that you will kill 100 workmen." This statemeut, while rather an ingenious one, is not, it is stated, borne out by facts. Take the Eiffel tower, for example. Six and a half millions' worth cost only four lives. The Forth bridge, on the other hand, a contemporary points out, cost 45,000,000 francs, while the lives of fifty-five men were sacrificed in connection with its construction.

Mechanical Progress.

Bell's Great Rival.

The biggest combination of capital and political influence ever gotten together has been organized to enter the telephone field and rout the Bell Company by giving cheaper, and, it is declared, better telephones.

The new enterprise is backed by the Sugar Trust, the Standard Oil Company, the Crocker interests of this State, and the Pullman Company interests. It has also among the men who are on the "ground floor" some of the shrewdest capitalists of every city in the Union.

Parallel with its line of capitalists is a line of politicians, who rank among politicians in the same fashion that the capitalists do among moneyed men. Among these are James S. Clarkson, of Iowa; John W. Candler, of Boston, Mass.; Colonel Conger, of Ohio; Representative Cannon, of Utah, the head of the Mormon Church; Louis Windmuller, of New York; Franklin Fairbanks, formerly Governor of Vermont; General Felix Agnus, of Baltimore, Md.; Charles A. Pillsbury, of Minneapolis, Minn.; and in Illinois W. J. Campbell, who also represents the Standard Oil interests; John S. Runnells, who also represents the Pullman interests, W. W. Tracy, of Springfield, Ohio, and two or three San Francisco men.

The entire country has been parcelled out and placed in the hands of local companies, each of which is organized along the double lines of capital and influence. The aggregate capital involved is $360,000,000. The amount of political influence is hardly calculable. It is safe to say, however, that it is enough to make any desired friendly legislation a great deal easier to obtain than it otherwise would be, and to make hostile legislation a great deal harder.

The company is named the Standard Telephone Company of New York. The electrical devices to be used are those of Allen T. Nye, who ten years ago made a long fight on the original patent covering the transmission of speech by means of a wire. He was unsuccessful then, but the expiration of that patent, about a year ago, gave him the benefit of what he tried to gain by litigation.

The company proposes to put in telephones at a uniform price of $25 a year, and make what is now a luxury within the means of comparatively few persons a necessity within the means of the great body of the public. The devices are already in use in New York City and State, and in New England.

Not the least remarkable feature about this gigantic combination is the secrecy with which operations have been conducted. This is the first intimation many will have of the plans of the company. It is doubtful if the Bell Company, with all its immense interests threatened, knows much, if anything, about what has been done by its rival in the actual operation of telephone lines.

The Standard Telephone Company is the parent organization, and there are nine local companies east of the Mississippi and ten in process of organization to cover the remainder of the territory in the United States, Canada and Mexico.

The Standard Company has a capital of $10,000,000, and offices at No. 68 Broad street, New York. Its board of directors is made up of Thurlow Weed Barnes, president; John A. Brill, president of the J. G. Brill Company, car builders of Philadelphia, Pa.; Carl F. Baker, of the hardware, steel and iron house of H. Baker & Co., of New York; John W. Candler, formerly Representative, railroad president and merchant, of Boston, Mass.; George Crocker, of this city; Henry Merz, president of the Heller-Merz Company, manufacturers of colors, of New York; Allen T. Nye, promoter of the company; Manning C. Palmer, president of the Syracuse National Bank and Electric Light Company, of Syracuse, N. Y.; Felix Rakeman, of Bulch & Rakeman, of Boston; John E. Searles, secretary and treasurer of the American Sugar Refining Company, better known as the Sugar Trust, of New York; Charles T. Strauss, of Charles T. Strauss & Brothers, importers of lace, of New York; and Louis Windmuller, of Windmuller & Roelker, of New York.

The State companies which have already been formed to operate as licensees of the parent company are the New York Standard Telephone Company, capital $6,000,000, to operate in the State of New York; Eastern Standard Telephone Company, Boston, capital $6,000,000, to operate throughout New England; New Jersey Standard Telephone Company, capital $3,000,000, Jersey City, to operate in New Jersey and Delaware; Pennsylvania Standard Telephone Company, Philadelphia, capital $5,000,000, to operate in Pennsylvania; Columbia Standard Telephone Company, Washington, D. C., Baltimore and Richmond, capital stock $4,000,000, to operate in Maryland, District of Columbia, Virginia and West Virginia; Ohio and Indiana Standard Telephone Company, Cleveland, Cincinnati and Indianapolis, to operate in Ohio and Indiana; Michigan Standard Telephone Company, Detroit, capital $4,000,000, to operate in Michigan; Northwestern Standard Telephone Company, Chicago, Davenport and Milwaukee, capital $6,000,000, to operate in Illinois, Iowa and Wisconsin; Northern Standard Telephone Company, St. Paul, Minneapolis and Pierre, capital $4,000,000, to operate in Minnesota, North and South Dakota.

The Central Standard Company, St. Louis, Kansas City and Lincoln, capital $5,000,000, to operate in Missouri, Kansas, Nebraska and Arkansas, is in process of organization, the promoter being Griffith Coit, president of the Union Trust Company, of St. Louis. The organization of the Mountain Standard Telephone Company, in Denver, Albuquerque and Salt Lake City, capital $4,000,000, to operate in Colorado, New Mexico, Utah and Arizona, is in the hands of George Q. Cannon, the head of the Mormon Church.

The local operating companies whose organization is not yet completed are: Southern Standard Telephone Company, Nashville, Louisville and Charleston, capital $4,000,000, to operate in Tennessee, Kentucky, and North and South Carolina; Gulf States Standard Telephone Company, New Orleans, Atlanta and St. Augustine, capital $5,000,000, to operate in Georgia, Florida, Alabama, Louisiana and Mississippi; Texas Standard Telephone Company, Austin, Galveston and Guthrie, capital $4,000,000, to operate in Texas, Indian Territory and Oklahoma.

Pacific Standard Telephone Company, Portland, Tacoma and Helena, capital $5,000,000, to operate in Washington, Oregon, Montana, Idaho, Wyoming and Alaska; California Standard Telephone Company, San Francisco, capital $4,000,000, to operate in California and Nevada; Intercolonial Standard Telephone Company, Quebec, St. Johns and Halifax, capital $2,000,000, to operate in all British territory east of the Province of Ontario; Canadian Standard Telephone Company, Montreal and Ottawa, capital $2,000,000, to operate in the Province of Ontario; British Columbian Standard Telephone Company, Vancouver and Victoria, capital $2,000,000, to operate in the British provinces west of Ontario; Mexican Standard Telephone Company, Mexico, capital $2,000,000, to operate in Mexico.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

AROUND FORBESTOWN.—The Golden Queen mill has resumed work. The company have been taking ore out of the Honeycomb for two or three months past.

AT HURLETON.—D. A. MacDonald, who has been superintending operations at the Pactolian, is here to buy machinery for further development of the mine.

THE DUTCH RAVINE MINE.—*Times*: L. A. Russell has bonded the Dutch Ravine mine, and is making preparations to begin work on it soon. This mine was opened some years since by Harry Stow and others and about $15,000 was spent in sinking a double compartment shaft down 150 feet and in building tunnels and drifts, of which there are about 350 feet. The ore assayed high and the ledge run from five to nine feet in width; but Stow was engaged in the Gold Bank tunnel scheme, and not having time to attend to both, the Dutch Ravine was bonded to Mr. Russell. This mine is near Hurlcton and is considered one of the best prospects in the country. It is in a good location and should give employment to a considerable number of men. The ravine in which the ledge was discovered was extremely rich in placer gold in early days.

AT CHEROKEE.—It is expected that as soon as the litigation over the Spring Valley mine at Cherokee is settled, which will probably be in a short time, the mine will be started and worked by means of drifting. This mine has always paid handsomely, but the injunction against hydraulic mining forced the mine into expending large sums of money, and eventually to be involved with its creditors. These matters being now adjusted, it is expected operations on a large scale will commence before long.

The ledge of the Big Betsy, in the Mooretown district, has been struck at a depth of 140 feet. The tunnel was in 175 feet, and work had been in progress some six months.

Calaveras.

THE TULLOCH MINE.—*Echo*: The Tulloch mine, situated in Albany Flat mining district, has, during the week, been put under agreement of sale within sixty days to M. Shaughnessy, of Salt Lake, Utah. If the party of the second part agrees to accept the property at the expiration of the sixty days, the mine will be transferred and a deed issued to Mr. Shaughnessy upon the payment of $50,000 cash in hand. The mine is not under bond and will not pass into the hands of any one until the sum of $50,000 is paid down. Mr. Tulloch is working the claim pending the consummation of the sixty-day proposition.

Nevada.

TULLYS' HYDRAULIC MINE.—*Transcript*: N. and J. B. Tully will start up their hydraulic mine, in the vicinity of Omega. They are building the necessary dam to restrain the debris from the mine before a permit from the U. S. Debris Commission can be obtained, and have chosen Scotchman's creek for the location of their dam, which is now about two-thirds finished. The dam will be 290 feet in length, 65 feet high, and the base of the supporting wall will be 120 feet in thickness.

A GOOD MOVE.—*Herald*: George Senn, superintendent of the Gracie mine, on Gold Flat, has made arrangements for the purchase of the mill, hoisting machinery and chlorination works of the Delhi mine, ou Columbia Hill. The entire plant will be removed to the Gracie and there utilized in working the ore from that mine. Mr. Senn represents an aggregation of strong capitalists, and has a bond on several other mines at Gold Flat. There is every reason to believe that extensive operations will be undertaken by the company. A boarding-house is now being erected near the Gracie mine.

WASHINGTON DISTRICT.—*Transcript*: The Oak Tree mine is extending the drift south on the 800 level, and have struck a good ledge of ore. Twenty-five men are at work, most of them stoping. In the stope the ledge is twelve feet in width. The mill is kept busy crushing the ore.

At the Blue Jay mine some excellent ore is being extracted from the stopes. Besides free gold the rock contains a large percentage of sulphurets that will yield about $80 per ton, and to save these the owners of the mine are putting up a canvas plant.

Messrs. Baugh, Bonuey and Heihergar will commence shortly to open up the Virginia mine. They iutend to run a drift on the ledge, which is about four feet in width, as shown by the prospecting already done. Tests made of samples of the ore lead the owners to believe that they have a very good mine.

In spite of the rumors of the resumption of operations at the Yuba mine, everything there is quiet—nothing having been doue as yet.

Several venturesome prospectors who, no douht, believe in the maxim "the early hird catches the worm," have already gone to work in the Fall creek country, though the snow is still from ten to twenty feet in depth.

The new pump at the Culhertson mine is working satisfactorily and handles all the water. Since the resumption of work a hody of ore has been struck that excels in quality even the rich rock heretofore obtained. The extent of the new find has not as yet been fully determined.

A 1700-foot tunnel is heing run by the Eric Mining Company, which will connect the Erie with the Duhlin Bay mine. The two mines are situated about half way between Gaston Ridge and Emeka.

San Bernardino.

THE DESERT QUEEN.—The latest reliable information, says the Banning *Herald*, in regard to the Desert Queen mine is to the effect that the seven tons of ore which have been milled yielded ninety-seven ounces of gold, which, at $17 per ounce, amounts to near $1700. This is an average of $240 per ton. James McHenry, of this mine, lately sent out a five-stamp mill. He reports the ledge in the Desert Queen a large one.

VANDERBILT DISTRICT.—The reports from Vanderhilt district are encouraging. The Gold Bronze mine is in good shape. On the 250-foot level there is 200 feet of ore in sight which runs up to the 150-foot level, the intervening distance heing nearly a solid block of ore. There is also good ore heing stoped out of the 150-foot level. A carload of concentrates was lately shipped from this mine to Pueblo. These concentrates are valued at ahout $60 to the ton. At present there are twenty-three men at work.

San Diego.

REDUCTION WORKS RESUMED.—The National City *Record* says that progress at the reduction works the past week has heen marked. The dry kiln is being lined with fire brick and the chimney for the kilu has been put up. The stamp mill, it is said, will begiu operations the first of this week. A steam siphon is to be used in draining the surplus water from the tailings, the water to he run off into the outside slough. It has been estimated that there are some 5000 tons of the tailings to he worked and ahout thirty tons a day will be run.

Shasta.

THE EUREKA TELLURIUM.—TO THE EDITOR: The new machinery at the Eureka Tellurium mine is heing put up at Middle Creek, Shasta Co. The wages paid to miners, machinists, engineers, etc., is $1.25 per day; board, $5 per week, to be paid from the wages.

GEO. E. MILLS.

GOLD DUST.—The *Free Press* is informed by the McCormick Saeltzer Company that since the first of January this corporation has shipped gold dust to the value of $1000 per week. Last year they shipped over $40,000. W. W. Williams shipped last week $600 in dust, and no later than Monday $300. Of course other firms ship some, hesides what is sent direct to the Mint through Wells, Fargo & Co. This does not mean amalgam, hut gold taken out of the placer mines and the river.

MINE BONDED.—E. P. Connor says that he has honded five claims on Salt creek to C. A. Hascall, late of Milwaukee, for $10,000. The bond is to run for a year. The company Mr. Hascall represents is to put up a mill, and Connor is to be paid from the net proceeds resulting until the sum agreed upon is paid over.

SOME RICH ORE.—C. W. Frost of Santa Rosa received a hag of specimen ore from a Shasta county mine last Thursday, which gave an average assay of $521.80 per ton in gold. He will erect a ten-stamp mill on the property. This will render the crushing of the ore very simple, as the mill can he operated by water power.

Siskiyou.

GENERAL MINING NOTES.—*Journal*: Messrs. Mullen & Kingshury, at the Spencer mine, on south side of the Siskiyons in Cottonwood district, are preparing to do placer work helow their quartz claim to gather up some of the stray nuggets that are certain to have washed down from the rich ledge above. They will get iron from the city and run a hydraulic.

Hippler & Roberts have sold their prospect claim in Humbug district to Tehhe and Davis for $500.

T. Franklin aud N. Lamh have bought the five-stamp mill of Cleland, at Barkhouse.

At Cherry Creek, Barnes & Co. are crushing about fifty tons ore with their two arrastras.

The Espey Mining Company have acquired an interest in the mines on Horse creek, and will put fifty meu at work digging a ditch that will carry 1000 miner's inches of water, and long enough to get 300 feet pressure. Horse creek has its source in the Siskiyous and is one of the trihutaries of the Klamath river. In March, 1894, an old channel was discovered ahout 100 feet above the present creek level. Considerable development work has since been done with results satisfactory euough to warrant the ahove undertaking.

This has been the most favorable spring in many years for river mining, and from the mouth of Cottonwood creek to the mouth of Scott river, (the river-mining section of the Klamath), many wheels may be seeu turning and hundreds of lahorers putting in wheels and wing dams and getting ready to take from the river heds and banks gold for which the Klamath river is famous.

The Eastlick Bros. and the Wright & Fletcher hydraulic elevators at Oro Fino are working at full hlast. The former have, owing to the favorahle spring, gotten a start of a month earlier than usual and expect hy July 4th to clean up $25,000.

There is some prospect of the Virginia Bar mine heing again put into operation. In the summer of 1888, a crowd of Kanaka miners took out $60,000. They afterward got off the pay, and since then no great effort has been made to find it.

The Klamath, Scott, Shasta, and Salmon rivers are running red with placer dirt.

In 1893 one-sixth of all the gold in the State received at the Mint, came from Siskiyou and Trinity counties.

Extensive mining operations are contemplated in the vicinity of Callahau's rauch, in the southern part of this county. Large tracts of old drifting ground has been acquired, and a long ditch is to he constructed bringing water from the south fork of Scott river and Jackson lake, and the property hydraulicked on an extensive scale. The enterprise is in charge of the same parties that brought water iu by an eleven mile ditch from Canyon creek to a 1300-aere tract uear Junction City in Trinity county, and sold the same when in operation to a French syndicate.

Work of digging the fifteen mile ditch to carry water from Clear creek to the Frazier diggings on the lower Klamath, is being pushed to completion.

Messrs. Songer and Dame of Ashland, Oregon, who have leased the McCoonell and and Quinn and Pacific mines on the Klamath river at the mouth of Humhug creek, have gotten them almost ready to commence operations. The former mine has in fourteen seasons produced $300,000 and but four of the forty acres have been worked.

J. M. Patterson, of Sawyer's Bars has purchased the six-foot ledge known as the Swede prospect, and expects to push work on and make some money out of his new claim. The Golden Everett mine has started up and also the mill. The Uncle Sam mine and mill are under full headway, and the mining outlook in general throughout that country never looked more promising, and the residents feel highly elated. The Corbin & Fitz mine is preparing to start soon, and there is talk of putting on thirty or forty men.

Trinity.

CENTER AND VICINITY. — *Journal*: The Trinity Gold Placer Syndicate have had twenty-two men employed all winter on their property on Coffee creek on very good gravel, taking out an avorage of $10 per day to the man. Last fall pipe was laid and other ditches cleaned out preparatory to sluicing in the spring. The company will employ forty or fifty men there this summer.

The Rainbow Company have opened a drifting claim on the old Henley claim on Coffee creek. They are getting out timhers and will push work rapidly as soon as the ground is sufficiently dry.

At Cinnabar, the Altoona Company have had sixty men at work all winter. A shaft has been sunk 135 feet helow the old workings and levels run from the bottom of the shaft, striking two large ore bodies, a ledge of hard cinnabar ore twenty feet in width, hoth very rich in quicksilver. Tunnels are being run and the property is being thoroughly developed. The furnaces are in operation and are turning out a stream of quicksilver. A defect in the flue of the furnace retarded the production of metal last winter, but that is now remedied and the furnace is run to its full capacity. The company will sink the main shaft deeper and show up the immense ore bodies of the mine. They have on the mine hoisting, sinking and pumping machinery to sink the shaft to a depth of 1000 feet. At the lntogral mine six men are at work prospecting and doing development work and taking out ore. More men will be put on soon and work will be pushed.

THE BROWN BEAR.—The Brown Bear Company have cut the ledge in the Monte Cristo in the lower crosscut from the lower tunnel—ahout 100 feet lower than the mill. The ledge is four or five feet wide, rich in free gold and sulphurets.

Tuolumne.

THE SOULSBY MINE.—E. H. Schaeffle has interested Michigan lumber capitalists in the famous old Soulsby mine of Tuolumne county. Their superintendent, Mr. Alvin Lundherg, with his engineer, Mr. Roth, are now on the mine arranging for its reopening. Tho Soulsby Cons., when in operation, was the leading mine of the county and yielded about three million dollars from its fifteen-inch vein of thirty-five-dollar ore. The mine was then a steady yielder of large dividends. With the improvements that have since followed in the methods and machinery for mining and milling, coupled with the great reductions in the cost of all operating expenses, and with four thousand feet of virgin ground to operate in, the mine should now excel its former record. Thus, one after another, the famous old mines are heing reopened—first the abandoned Kennedy, which is to-day the leading mine of Amador county; then the Utica of Calaveras, now the banner gold mine of the United States; then tbe Rawhide of Tuolumne, now producing the richest ore of any mine in the State; next the Hite of Mariposa, Gwin of Calaveras and now the old Soulsby of Tuolumne. All that any of these mines wanted was depth, which has brought them into honanza, and with modern mining and milling methods made the mines, that are now fully equipped and developed, the largest dividend producers of the State.

THE JUMPER MINE.— *Independent:* A rich strike was made on the mother lode at the above mine, at Chilli Hill, last week. From the result of one hlast, in the No. 1 level, $3000 was dislodged and daily exceedingly rich ore is coming to grass. The body of ore that produces this rock is carried eleven feet wide, hut it is believed the ore body is much larger, which will be so found when more fully explored. Judging from the surface indications, the pay helt will be found twenty or more feet wide, being in hlack mineral slate formation. The last cleanup from their new ten-stamp mill yielded $12.50 per ton. A good deal of the rock sent to the mill was considered as waste. The result surpassed the owners' most sauguine expectations. None of the rich rock has been treated as yet, of which there is a considerable quantity on hand that will mill $20,000 per ton.

NEVADA.

STOREY COUNTY.

The following official reports have been placed on file in their respective offices:

CHALLENGE.—From the surface tunnel the joint Confidence and Challenge raise is up 63 feet; the top is in quartz of no value.

CROWN POINT.—The south drift from the raise on the 700-foot level was extended to a total length of 20 feet and counected with the fourth floor north drift. Work was resumed in the raise from the east crosscut from the south lateral drift on the 700-foot level, and it is now up 40 feet. The top is in a mixture of porphyry, clay and seams of quartz. Have been engaged in retimbering and repairing the south drift from the east crosscut on the 700-foot level and have completed 37 feet. During the week have shipped to the Mexican mill 670 tons of ore which was extracted from the openings hetween the 600 and 700 foot levels and from above the 600-foot level. The average hattery for the week was $10.48, of which $9.35 was gold.

BELCHER.—On the 300-foot level the joint Belcher and Seg. Belcher south drift is in 166 feet from the shaft; the face shows porphyry. Have hoisted during the week forty-five tons of ore, the average top-car sample of which was $16 29 per ton. Have also shipped to the Brunswick mill for reduction 301 tons of ore.

SEG. BELCHER.—On the 200 foot level the southwest crosscut from the south lateral drift is out sixteen feet; the face shows porphyry and quartz of no value. Have hoistcd during the week and stored in the orehouse at the mine twelve tons of ore, the average car-sample of which shows an assay value of $34 46 per ton.

JUSTICE.—The north prospecting drift from the hottom of the Blaine winze, intermediate tunnel level, was advanced ten feet. On the drain tunnel level, between No. 1 and No. 2 chutes, they are sinking a winze in the ore mentioned in the last weekly report. This winze is now down 12 feet in fair-grade ore.

SAVAGE.—On the 950-foot level the north lateral drift, started from the west side of station, is advanced 25 feet in the vein. The east crosscut, started from the south drift 40 feet back from the 13th-floor upraise, was advanced 25 feet when it reached the last clay of the ledge and was discontinued. The north drift, started from the east crosscut, fourth floor of north upraise, is advanced 24 feet; face is in quartz and porphyry. The south drift from the face of the sill floor, southeast drift, was advanced 20 feet; total length, 100 feet; face in quartz, giving low assays. On the 1000-foot level they are extracting some ore on the 8th floor of the old stopes. On the 1050-foot level the east crosscut, started on the fourth floor, 300 feet south of the shaft, is advanced 25 feet; face is in quartz, giving low assays. Have started a west crosscut from the tenth floor of the south ore slopes, and advanced some ten feet in quartz.

LANDER COUNTY.

AUSTIN MILL TO START.—P. L. Farusworth says the mines are in a flourishing condition. The ore produced is a free-milling silver ore—one of the cleanest and best milling ores in the State—and on this product the company's mill will start up next week.

ALASKA.

PRICES AND PROSPECTS.—Juneau *News*, April 4: A prospector's supply for one year in the Yukon country should consist of about the following, whereof comparative prices are given in the table below:

ARTICLES.	No. of Pounds.	Juneau Prices.	Forty Mile Prices.	Total cost Juneau.	Total cost Forty Mile.
Flour	450	2	$ 08	$9 00	$36 00
Sugar, D. G.	75	5½	20	4 13	15 00
Bacon, side	75	10	35	7 50	26 25
Bacon, breakfast	25	13	50	3 20	12 50
Beans	75	3½	10	2 62	7 50
Dried Apples	25	10	20	2 50	5 00
" Peaches	25	10	30	2 50	7 50
" Apricots	25	10	30	2 50	7 50
" Prunes	25	10	30	2 50	7 50
Raisins	25	10	25	2 00	5 00
Split Peas	25	8	15	2 00	3 75
Coffee, ground	10	25	40	2 50	4 00
" green	5	50	50	1 50	2 50
Tea, common	10	35	75	3 50	7 50
Baking Powder	12	50	1 00	6 00	12 00
Condensed milk, ½ case	30	....	....	8 37	10 00
Corned Beef, 1 case	28	....	....	2 75	6 00
Cornmeal	10	3½	15	35	1 50
Rolled Oats	10	5	15	50	1 50
Oatmeal	10	5	15	50	1 50
Rice	35	7½	15	2 62	5 25
Evaporated Potatoes	10	25	40	2 50	4 00
" Onions	5	50	1 00	2 50	5 00
Black Pepper, ground	2	50	1 00	1 00	2 00
Salt	15	10	10	37	1 50
Mustard, ground	1	40	1 00	40	1 00
Allspice "	½	25	50	25	50
Cinnamon "	½	50	75	38	75
Sage "	½	35	50	35	50
Butter, roll	15	40	1 00	6 00	15 00

Gum Boots, C P	8	....	....	6 50	12 00
" canvas	6	....	....	3 50	10 00
Juneau Sleigh	20	....	....	8 00	16 00
	1,132			$107 70	$280 50

It will be remembered the above is a pretty comfortable and complete outfit, and might be cut down some; however, a prospector will find use for it all if he has it. In the line of dry goods and clothing add 75 to 125 per cent, and you approximate Forty Mile prices.

And now a few reasons why all who come in should either bring a complete outfit with them or cash to huy the same on landing here. There are only two companies doing business in the way of transporting goods to this country; that is to say, from St. Michaels, at the mouth of the Yukon, to Pelly river, a distance of 1700 or 1800 miles. The Alaska Commercial Company runs the steamer Arctic, whieh carries about 100 tons of freight and is supposed to make three or four trips a season and to land enough goods to supply her traders with all the merchandise their customers require, hut they often run short. The Arctic made three trips last summer, hut the fourth she failed to get here. This was truly unfortunate for Messrs. McQuestou & O'Brien, Harper & Ladeau and Harper, the Commercial Company's traders. The Arctic had on hoard 2000 sacks of flour and a proportionate quantity of other supplies, all of which she landed at Fort Yukon, within the Artic circle, about 300 miles, by the river, below Forty Mile and ahout 80 miles below Circle City. Last fall between the two trading companies some prospectors got their full supply for the year, but there were more who secured only a partial outfit—

in fact many were cut down to 100 pounds of flour and some hard tack, with a few pounds of other provisions. This will put the camp back one year, no doubt.

No one should think of coming here unless he is a strong, ambitious and energetic man, willing to work hard and undergo many hardships, privations and disappointments without becoming discouraged. There is much hard work to be done by the prospector, such as poling his boat up rivers and creeks to the nearest point to the locality where he intends to work or prospect, and from the landing he may have to pack through swamps and over mountains from ten to fifty miles, fighting and battling more mosquitos, black gnats and black bugs than he ever saw; unless he has been here before.

Prospectors and miners who have been in here one season avoid much hardship by sleighing their goods in winter time by dog teams or pulling their sleighs themselves. Freighters who run dog teams charge ten cents per pound from Forty Mile to Franklin Gulch, 85 miles up Forty Mile river, and the same price to Miller or Glacier creek, on the head of Sixty Mile creek, 60 or 70 miles distant. To have goods packed to these places in the summer time costs from 30 to 40 cents per pound. The additional price is owing to rough trails through marshes, over divides, crossing creeks, etc.

Gold has been found on the bars of the Hootalinqua, a distance of 150 miles above its mouth, but not in paying quantities. At the head of the river there are some large lakes and the country is flat and marshy. The river is large and the water runs swift, making it hard work to pole up. The Little and Big Salmon rivers have been prospected along the bars and some gold taken out.

William Ebner has sold to the Seattle & Alaska Mining and Milling Company the Tennessee and Lindig mines in St. James Bay district for 30,000 shares of stock in same and $2500 cash.

ARIZONA.

KING SOLOMON.—Reports from the King Solomon district, ten miles east of El Dorado, Ariz., are to the effect that the veins lately uncovered there indicate a low grade of porphyry and iron formation, showing, by assays, from $2 to $16 per ton in gold. Some are of the opinion that the ore, of which, as reported, there is an immense quantity, can be milled in the mountains, while others contend it will have to be brought to the river. Franconia, on the Atlantic and Pacific, is the nearest station, being about seven miles from the district.

SILVER KING.—News from the Silver King, says the Florence *Tribune*, is encouraging. The recent report of a rich strike on the 400-foot level seems to have a good foundation. It is said that native silver, similar to that which made the mine famous, has again been encountered in a large body. Arrangements to work the mine on an extensive scale are contemplated.

THE ARICA GROUP.—*Miner:* A. M. Wells of Denver, as agent for a wealthy syndicate of New York and Denver, has closed a deal with E. H. Hiller and C. H. Gray whereby these gentlemen convey to the syndicate the group of gold mines known as the Arica group. The syndicate will begin the work of developing the mines at once by building a railroad from the mines to the Colorado river and operate a steamer on the river. A twenty-five stamp mill will be erected at the mine, and with a large force of men and plenty of money to back the enterprise these mines may be expected to add much to the output of gold in the Territory for the future.

BRITISH COLUMBIA.

FAIRVIEW.—The Oro Denard mine has been bonded by W. T. Thompson for $30,000. This is one of the largest copper claims on the continent, having a width of 600 or 700 feet on the surface.

The Lead King mine has been bonded to Symonds & Wallace.

TRAIL CREEK ORE.—The Trail creek ore is dumped into wagons when it leaves the mine, without being sacked or sorted, says the Rossland *Miner*. In this respect it differs from the high-grade lead ores of the Slocan and from the copper-silver ore of Toad mountain, which are both carefully sorted before they are shipped. The ore is then transported to Northport, where direct connection is made from the wagon to the car, or to Trail, where a transfer by steamboat down the river is necessary. The road to Northport is fifteen miles long; that to Trail is short seven, but the transfer adds an extra dollar to the cost of shipment, and other things being even, all the ore would go by Northport. But other things are not even, for the Northport road is in very bad shape, and will remain bad till the spring rains are over. It does not pay teams to haul ore now, unless they have freight to bring back.

The ore is then shipped by rail to the smelter. Most of it hitherto has gone either to the Montana Sampling and Refining Works at Great Falls, or to the Tacoma smelter. Because of its excess of iron, which amounts to about 25%, the ore is exceedingly valuable to the smelters as a flux, and as it saves them buying iron ore they are willing to pay a premium for it. Before the ore can be smelted the sulphur has to be roasted out of it, and after roasting it is mixed with silver ores and smelted.

COLORADO.

PARK COUNTY.

Alma districts have eight mills and concentrating plants, and one sampling works, with plenty of milling and shipping ore in sight, says the Park County *Bulletin*. Most of the largest bodies of ore are gold bearing, while others are rich in silver and carry a small percentage of gold, with heavy percentages of lead and iron. Smelters are treating some of the Alma ores now free, and others at as low a rate as $1.50 per ton, and, with the low freight rates, what more could be asked or expected for a boom starter.

IDAHO.

THE TIGER.—*Miner:* They are building a new ore bin which will hold about 500 tons, sufficient for a several days' run of the concentrator. The Tiger is now employing sixty-five men all told.

THE GEM.—The shaft at the Gem mine has been sunk to a depth of 100 feet below the first level from the tunnel, or 235 feet below the tunnel level. There a crosscut will be run to the lode.

THE POORMAN.—The Poorman has about 180 men on its payroll. The monthly disbursement is about $20,000.

The continued operation of the mines at Burke, when a number of the leading mines throughout the country have been obliged to close on account of low prices of the metals, is presumptive evidence of the great value of the mines.

RECLAIMING AMALGAM.—A Scotch company is putting in a big bedrock flume on Bear creek, near Rocky bar. The flume has already been built a considerable distance, and its construction has developed a most interesting fact, but not an unexpected one. In the early days there was a number of arrastras and quartz mills in operation on the creek above the point where work on the flume is now being done. Large quantities of amalgam had been allowed to escape into the creek, and it was thought enough could be secured by means of a flume to make the enterprise remunerative, even though no other gold were discovered. Already considerable amalgam has been taken out, and the flume is still two miles below the point where most of the mills and arrastras were located. It is estimated there is at least 250,000 pounds of amalgam in the creek that can be saved by means of the flume. Every 100 pounds of the amalgam contains about five pounds of gold, or about $1250.

MONTANA.

PIPESTONE DISTRICT.—The Columbia mine, in the Pipestone district, is sold, says the *Zephyr*, to C. E. Van Zandt, of Butte, for $20,000. Stamps will soon be dropping on the Columbia ore.

BOSTON & MONTANA.—It is thought that the next dividend on Boston & Montana stock will be $2 per share, payable in May. The rise in the price of silver is a good thing for the Montana and the Butte mines, as they produce a large amount of the white metal. The Montana produces about 15,000 ounces monthly and the Butte 90,000 ounces. Each advance of one cent in price of silver means a much larger revenue for those two companies without any additional expense. With silver at 67 cents, the Butte's income from its silver must be $700,000 per annum, which is equivalent to $3.50 per share on the stock.

AT LUMP GULCH.—*Review:* A new kind of mineral known as molybdenite has been discovered in Lump gulch in the G. and P. mine, owned by Thomas Greenwood. This rare metal very much resembles antimony and occurs in short or tubular hexagonal prisms, and is valued at $58 per pound in Germany.

BOUGHT THE MCVEY PROPERTY.—Helena *Independent:* Charles D. McLure of the Bi-Metallic and Granite mines has purchased the McVey property, adjoining the Chili, situated at Sand creek, Granite county. This property runs about $109 in gold. The shaft is down about 300 feet. $12,000 was the amount reported for it.

NEW MEXICO.

GENERAL NOTES.—Cerillos *Rustler:* The machinery for increasing the daily capacity of the Fitzgerald test works at Golden is in place.

James M. Lucas, who has been running a stamp mill on the Fuerto for some eighteen months with very satisfactory results, made a cleanup last week. The proceeds of a fifteen-days' run were an even $1500. That is pretty good—$100 a day—with a small, cheap five-stamp mill.

New Mexican: There are now working in the Pinos Altos camp four quartz mills and one at Silver City working on Pinos Altos ore. There are about 200 men employed in the camp, all working on contract and making good wages. The men are breaking ore by the ton and driving drifts, etc., by the foot. The ores are not to say very high grade, but can be worked at a fair profit. The veins are true fissure veins, in granite and porphyry. At a depth of 600 feet the fissures are as well defined as at the surface.

NEW DRY-WASHER.—A New Mexico man has patented a dry-washer, designed to save all the gold, both flour and nuggets, in the sand without the use of water and quicksilver. It consists of a sand-roaster discharging into a nugget separating machine leading to conveyors connected by elevators with the uppermost of a series of screens one above the other, each having riffles to retain the gold and an outlet for the tailings. The screens are graduated and each has a hopper discharging into the next lower screen. The machine is run by a team attached to sweeps.

NORTH CAROLINA.

A Raleigh dispatch says: Gold miners from the West are arriving at Piedmont section of North Carolina and there is an outbreak of mining fever. The discovery of a nugget weighing eight pounds five ounces in Stanley county has increased interest in mining.

OREGON.

JACKSON AND JOSEPHINE COUNTIES.—Dysert & Miller are opening some promising placer mines on Jack's creek in Josephine county, which they expect to work on an extensive scale next season. They are building a ditch to carry water from Jump-off-Joe creek.

Dugan & Colvig have a small force at work developing their quartz ledge west of Jacksonville, which is getting richer and better defined. They are exhibiting some very fine ore.

Capt. Nash was at Althouse, Josephine county, last week, where he put a hydraulic plant into shape for the Rosoburg company which is operating in that section. They have a supply of water and plenty of ground.

The old channel in Humbug district, Applegate precinct, which was so rich in early days, has again been discovered by a miner named Poole, who has been drifting there for some time past. He has taken out about $1500 since he struck it.

CINNABAR MINE.—Ashland *Tidings:* The Minneapolis people, who had Hill's cinnabar mine on upper Wagner creek bonded, allowed the bond to lapse last month. Hill has since been running a new tunnel in on the ledge. The ore carries gold as well as quicksilver.

UTAH.

CENTENNIAL-EUREKA MILL.—It is more than likely, says the *Tribune*, that the prosperous Tintic district will have another big reduction plant before the season is over. The Centennial-Eureka Company has about decided to erect a concentrator, for the purpose of handling the large amount of concentrating ore that the mine is producing now. The mill will be of at least 100 tons capacity, but no definite plans have yet been decided upon.

The strike recently reported on the 1000 level of the Centennial-Eureka is not considered by local stockholders a matter of unusual importance. New bodies of high-grade ore are constantly being developed, they say, and have become quite an ordinary matter in this mine, which has become one of the great producers of the country. The regular monthly dividend of $1 per share was paid on Monday, $30,000 being distributed. The Centennial-Eureka is now the banner dividend-payer of Utah, but the Silver King and Bullion-Beck will give it a close race for first place before the year is ended.

WASHINGTON.

ON THE CHEWAHWAH.—Messrs. Wilson & Powers of Seattle have a force of ten men at work establishing hydraulic works with which to engage in placer mining on the Chewahwah and expect to be washing black sand in copious quantities by the 1st of June. It is asserted that from twenty to thirty good colors can be obtained in every pan.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from T. G. Phelps, in the Liberty Hill mine, Nevada Co., and John Spaulding, in the Polar Star mine, near Dutch Flat, Placer Co., to impound tailings behind the Liberty Hill dam, in Bear river; and from Ah Wing, in the St. Lawrence mine, near Moores Flat, Nevada Co., to impound tailings behind brush dam in Illinois canyon, gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, Cal., on May 13, 1895, at 1:30 P. M.

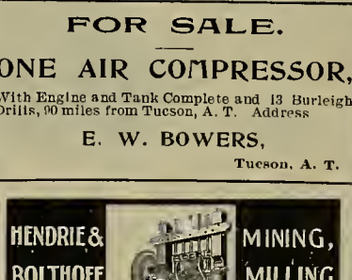
FOR SALE.

ONE AIR COMPRESSOR,

With Engine and Tank Complete and 13 Burleigh Drills, 90 miles from Tucson, A. T. Address

E. W. BOWERS,

Tucson, A. T.



INVENTORS, Take Notice!

Gold and Silver Refinery

—AND—

Assay Office.

HIGHEST PRICES PAID FOR GOLD, SILVER AND LEAD ORES AND SULPHURETS.

Manufacturers of

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

Also Manufacturers of

STANDARD SHOT-GUN CARTRIDGES, Under Chamberlin Patent.

John Taylor & Co.

Importers and Dealers in

Assayers' Materials,

Mine and Mill Supplies.

Also Chemicals, and Physical, School and Chemical Apparatus.

63 & 65 First St., Cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc. Including, also, a full stock of Chemicals.

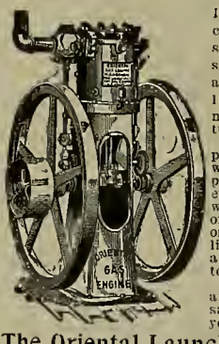
M.C.C. BATTERSEA

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the **Denver Fire Clay Co.** and for the **Morgan Crucible Co.**, Battersea, England. Also for **E. G. Denniston's Silver Plated Amalgam Plates.** The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

The Oriental Gas Engine



IS THE BEST because it combines simplicity of construction with power and economy of space. It can be run with natural or manufactured gas or gasoline.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

M. A. GRAHAM,

Inventor and Manufacturer,

105 Beale Street..... .....San Francisco.

FOR SALE.

ONE PUMPING PLANT.

One Quadruple Force Pump; two Cornish Pumps; one Corliss Engine, 150-horse power; and five miles of 4-inch Pipe with converse look joint. Address

E. W. BOWERS,

Tucson, A. T.

Adamantine Shoes and Dies

—AND—

CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

These castings are extensively used in all the mining States and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to the above conditions. When ordering, send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS & CO., Agent, 141 and 143 First Street, San Francisco.

Stamp Cam

FRANCIS SMITH & CO.,

—MANUFACTURERS OF—

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

130 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Electrical Progress.

Tesla's Oscillator.

Countless are the directions in which Nikola Tesla has experimented, but there are four things with which, in the minds of people familiar with his labors, he is particularly identified. He has introduced an entirely new system into the operation of dynamos and motors by causing what is called the "magnetic field" to revolve and drag the armature along with it. This is an improvement of immense practical importance in the transmission and use of alternating currents for power purposes, and is alone sufficient to render him famous for generations. He has shown that alternating currents of tremendously high potentials may be handled with practical impunity under certain circumstances—an exceedingly brilliant achievement, although of less practical value than some others. Then he has very nearly, if not quite, solved the problem of producing electric light without heat—an object which numerous scientists have eagerly sought with little result so far, but which is highly desirable in the interests of economy, to say nothing of safety and beauty. Finally, he has invented a combination of steam engine and dynamo, called an "oscillator," which is designed greatly to simplify the mechanism necessary in generating electricity, and hence to revolutionize that art. Several specimens of this device, differing among themselves in form but not in principle, were publicly exhibited and explained by Mr. Tesla nearly two years ago. He has since improved it in detail, with a view to still greater simplicity and efficiency, and it is said that just before the fire which destroyed his laboratory, a few weeks ago, this invention had reached such a degree of perfection that it was ready for the commercial stage of its career. Although some of its less important features are still kept private, and while it is impossible yet to measure with accuracy the possibilities of its usefulness, the oscillator is just now attracting renewed attention and provoking much enthusiasm among electrical engineers.

The fundamental idea of this machine is that the coils of wire in which a current is excited are moved to and fro horizontally, instead of being whirled around by a rotating shaft. What electricians call the "field" is the area in front of the poles or pole pieces of a magnet. Out into that space there extend invisible "lines of force." If a piece of soft iron be moved transversely past these poles, and near them, cutting the lines of force, it is momentarily magnetized by induction; and in any coil of insulated copper wire surrounding it, there is induced, for the same brief instant, an electric impulse. In the ordinary dynamo a ring of soft iron is used instead of a bar, a number of connected coils are wound on it, and the whole "armature" is revolved between and in very close proximity to the field magnets; but Mr. Tesla winds his coils on a straight bar, and oscillates the latter between his magnets. By this change of method, he is able to accomplish several things not secured by the ordinary dynamo.

One of the most exquisitely beautiful, as well as essential, features of the oscillator is yet to be mentioned. It is desirable that the frequency of the alternations in a current—its "period," as the experts call it—shall remain constant in the face of all variations of "load," or work demanded of it. This can be regulated with a spring of the proper stiffness attached to the oscillating rod. An "air spring," consisting of a piston inside an air-tight cylinder, may be made to perform this office, and the supplementary cylinder may be situated either close to the working cylinder or at some distance away, both pistons, however, being secured to the same rod. Again, proper air chambers at the end of the working cylinder may be made to serve as springs. By proportioning the size of the chamber of the air spring to the weight of the moving parts, the desired period is produced. Greater or less pressure of steam and any fluctuation in load may affect the length of the stroke, but not the frequency. There is still another mode of regulating the vibrations. It has been shown that electrical currents exhibit certain phenomena resembling those of sound. A circuit of a given "capacity" and "potential" is more favorable to vibrations of one frequency than any other. An instrument known as the "condenser" can be introduced in to an electrical circuit to "tune" the latter to the desired frequency of oscillation—thirty, fifty, eighty or any other number per second. Mr. Tesla has applied this principle of "resonance" to some of his experimental oscillators, and thus imparted to his apparatus a selective affinity for whatever rate of vibration he wants. This is an automatic governor which corrects any tendency to fall below or exceed the required speed. With such precision will this period be maintained that a clock may be driven with an oscillator and keep good time.

Reducing Electric Voltages.

There are several reasons why it may be desirable at times to change the voltage of an electric current. Perhaps for convenience in transmission, a higher voltage is used than is required by the consumer, and hence reduction is necessary at the end of the line. Again, several users, having a common source of supply, may require different voltages. The so-called "transformer," used only with an alternating current, consists of a motionless piece of apparatus—two coils of insulated copper wire, one inside of the other. The primary current flows in one, and the secondary, or induced, current in the other; and the proportion between the voltages of the two is regulated by that between the number of turns of wire in the respective coils. But this mechanism will not do for a continuous current. Instead, it is customary to use a combination of motor and dynamo, called the motor-dynamo. This calls for two sets of windings with wire on the armature or rotating part, the primary current flowing in the one and the secondary in the other. There, again, the respective voltages are proportioned to the number of turns of wire in the coils. Two commutators are necessary, too, on the axle, one leading the primary current in and out, and the other serving the secondary current similarly. In both the induction coil and the motor-dynamo, such conversion as has just been described alters the amperage (volume) at the same time as the voltage (pressure), but in the opposite direction.

It is announced that a new device for transforming a continuous current has been invented by J. J. Hogan, who is connected with the mechanical department of the psychological laboratory of Yale University. It is said to be much more simple and inexpensive than the motor-dynamo, but equally effectual. Within a few days tests of the apparatus have been made in the presence of expert electricians, representing various telegraph and telephone companies; and these men are quoted as admitting that the invention is a bona fide affair, and not a "fake" nor the product of a crank's fancy. It is claimed also that Mr. Hogan's method wastes less current than the one which it is designed to replace. Still further, it is adapted to the reduction of any voltage, no matter what, to any other voltage. This is an important advantage, since the motor-dynamo has to be wound with special reference to the work it does, and then will reduce only from a given figure to another predetermined figure. Mr. Hogan's apparatus is universal in application, and is regulated by the simple turn of a thumb-screw. For the present, however, he prefers not to have a detailed description published. Finally, it is claimed that this converter does not raise the amperage when reducing the voltage, but leaves the former unchanged.

TAUGHT BY MAIL THOROUGH PRACTICAL

THE AMERICAN MINING & MILLING MACHINERY CO.,

121 Euclid Ave., CLEVELAND, O. 280 Caxton Blk., CHICAGO, ILL.

SPECIALTIES:

AM. CRUSHER AND AM. BALL PULVERIZER.

The simplest, cheapest and best machines in the market. Pulverize wet or dry to any degree of fineness. Make little or no slimes in wet nor dust in dry work. Four sizes, capacity from 2 to 60 tons per day.

SEND FOR CATALOGUE. Cable Address, American.

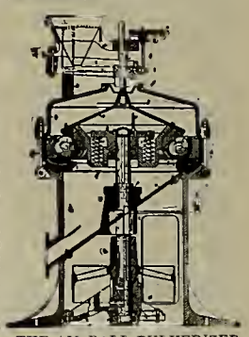
First Prize and Gold Medal Awarded by World's Fair, 1893.

Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O., Jan. 25, 1894.

The American Mining & Milling Machinery Co., Cleveland, O.:

GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4¾ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows less; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with less than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,

CLEVELAND IRON ORE PAINT CO.



THE AM. BALL PULVERIZER. Morris Patent.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

A Machinist's Arm Filled With Wire.

The latest surprise in surgical operation, says a New York dispatch, is the removal of eleven feet two inches of one-sixteenth-inch wire from a man's body. This operation was performed at Bellevue by Dr. Rathbun, assisted by the house staff. The case is one of the most peculiar on record.

John Scanlan, a machinist, thirty years old, had worked several years for the East River Lead Works. Among other things manufactured there is lead wire, used largely for wrapping purposes, and by electricians. The lead wire is made by forcing a mass of metal through a die under a hydraulic pressure of 600 tons. The metal is hot, but cools as it is forced through the die in the shape of a wire. Scanlan was at his post. The machinery suddenly stopped. The man leaned forward and grasped the wire already through when there was a loud report; the die, or a portion of it, was blown out, and Scanlan was knocked to the floor. When he recovered from his dazed condition he felt no pain except in his left arm. He went to Bellevue hospital a few hours later, where the surgeon found a small abrasion of the skin near the wrist and all the indications of a fracture of the elbow. It was determined to remove the portions of shattered bones supposed to be there and Dr. Rathbun began the work. The point of the surgeon's knife had scarcely gone below the cuticle when he stopped, looking very much astonished. Then he pulled out a piece of lead wire and kept on pulling until out of the three-inch opening in the flesh over eleven feet of wire were drawn. Yet there had not been the slightest break in the skin or wound of any kind, except the little abrasion already alluded to. The doctors think that Scanlan took hold of the wire, and the explosion following, the wire, driven with great rapidity, caught on his wrist and was shot into his arm, as by an immense hypodermic syringe. Being soft and malleable it struck the humerus probably and doubled up and down the forearm and was imbedded in the muscles.

The Passing of the Horse.

A prominent electrical company has collected some startling figures, which show the almost incalculable influence of the introduction of the electric car, taken merely on its one basis of replacing the horse for traction purposes. It is estimated that electric cars have already displaced 1,100,000 horses, and this estimate is manifestly far below the actual number. The feeding of these horses would entail the consumption of 500,000 bushels of corn or oats a day. The animals are now back on grass, and the enormous decrease in corn and oats consumption caused by their withdrawal is sufficient to appreciably affect the prices of those grains. In round figures, it amounts to 180,000,000 bushels a year. There is another view of this subject, the significance of which will be probably more appareut a few years hence than it is even now. The loss of commercial demand for these coarse grains in the cities means an enormous decrease in the tonnage of the railroad freight traffic. This failure is already put at a minimum of 250,000 carloads. But it is not only in public traffic that the day of the horse is waning. In some cities the electric car lines have been so judiciously distributed and give such excellent service that many private families have given up their carriages and use the electric cars instead. In many places the business of the liverymen is practically ruined by the electric car, and, as at Niagara Falls, the formerly arrogant and extortionate hackman has become a comparatively civil and temporizing individual. The electric car and the bicycle have sounded the knell of the horse as a commercial factor.

THE longest dry-dock in the world is now building at Glasgow, Scotland. It will be 900 feet over all, 800 feet from inside face of caisson, 74 feet in width at bottom and 115 feet at top, and 28 feet deep from average high-water springs to floor. The entrance is to be 83 feet wide, with perpendicular sides, and to have a depth of 26 feet from average high-water springs to sill.

The Manufacture Of Wild Men.

There are many curious trades in the world, but the most strange must surely be the "artificial manufacture of wild men." Yet a well-known English doctor in China has just certified from his own personal experience that this art is regularly practiced in the Flowery Kingdom.

First a youth is kidnapped, then bit by bit he is flayed alive, and the skin of a dog or bear grafted piece by piece upon him. His vocal chords are next destroyed by the action of charcoal to make him dumb, and the double purpose of causing "etiolation" of the skin and utter degredation of the mental faculties is effected by keeping him immured in a perfectly dark hole for a number of years. In fact, by treating him like brute for a sufficiently long time he is made into one.

At last he is exhibited to the entirely credulous Chinese as a wild man of the woods, and his possessors reap a rich harvest.

The priests, it seems, are adepts at the art. When a kidnapper, however, is caught by the people he is torn to pieces, and when the authorities get him they torture him and promptly behead him. Such is life under the rule of the Son of Heaven.

PATENT SOLICITORS.
ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, April 25, 1895.

Silver holds its own, aud a little more. That speculation more than permaneut advance characterized recent operations is evidenced by its unsteadiness. It is stated that China is to have six years in which to pay six installments of the war indemnity of 266,000,000 ounces silver, which would make that an additional annual purchase of 80% of the total product of this country.

A recent meeting of the Southern and Western rolling mill men, at which 87% of the total output was represented, it was agreed to steadily advance prices to an average of at least 10%. Mills are rejecting prices that ruled a week ago. Pig iron has advanced 25 cents a ton.

In their monthly report on ores and metals, James Lewis & Son, of Liverpool, England, under date of the 1st, write: Copper—After falling 8s 9d per ton on the 5th ult., from £39 2s 6d to £38 13s 9d, good merchantable copper closes 8s 9d higher for the past month, with buyers of cash at £39 11s 3d per ton. English and French public stocks are reduced 1755 tons, and the visible supply 1855 tons; the reduction in the private stocks here and on the continent must also he large. The advance of 3½d per ounce in silver has led to a good demand for manufactured copper for India, while Birmingham has taken considerable quantities of tough and best selected, and France has bought electrolytic copper. In American copper about 2000 tons of Lake and 1000 tons of electrolytic are reported as having been sold to the continent. After declining to 9.25 cents per lb, Lake is now quoted as 9.37½ cents, the demand for home consumption having improved. American shipments to Europe for the past month are only 3750 tons, making 14,423 tons for the first quarter of this year, against 20,444 tons for the same period last year. Imports are 1436 tons, and deliveries 2517 tons greater to date than during the same period last year. The arrivals in England from Chile during the month have been 1055, and the deliveries 819 tons fine, and from other countries 2758 and 3955 tons fine respectively. The arrivals in England from the United States have been 1064 tons bars and 140 tons matte, equal to about 1105 tons fine copper, and in France 506 tons fine. Quotations to-day are: Chile bars and good merchantable copper £39 11s 8d for casb, and £39 18s 9d for three months' prompt, buyers. English best selected ingots £43 to £43 10s, and tough cake £42 10s to £43 per ton. 7s 6d to 7s 9d for ore of 20%, and 7s 9d to 8s per unit for Chile regulus or American matte, free from silver.

It is reported in Euglaud that the recent scare as to the scarcity of platinum was got up for a purpose, and that the increase in price was due to a combination between some English users of the ore and a broker in St. Petersburg, who together controlled the production and got up a "corner" in this article. The increase in price has, however, provoked competition, and several new mines have been opened, which have increased the production considerahly. There are now at least forty mines at work in the Ural mountains, hut the plant employed is of a very primitive cbaracter. Some of the mine owners have now introduced steam power, hut at present the sand is not purified at the works, hut is being sent to an establishment in Germany, where it is prepared for the market. The yield of crude platinum for the year 1891 from the Ural provinces exceeds 9000 pounds, or fifty per cent more than the returns for the previous year.

New York Metal Market.

Mining Share Market.

SAN FRANCISCO, April 25, 1895.

A low range of values and quiet business characterized the week. The condition of the Comstock has improved and faithful work is being done, hut that never had much to do with the stock market and of late years seems to have even less. So long as it is not a question of control of certain mines, the present flatness may continue, or until some few with nerve and amhition step in to liven things up. Con. Cal. & Virginia, Ophir and Hale & Norcross were held up, and on Thursday Virginia City bought freely, the demand being as freely met by Pine street.

The following illustrates the changes of the week:

HIRAM S. MAXIM, the inventor, says that New Englanders are the best mechanics in the world, and that the French are the best mechanics in Europe.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING APRIL 16, 1895.

537,559.—WAVE MOTOR—W. N. Best, Redoudo, Cal.

537,448.—SAVINGS BANK—J. H. Greefkens, S. F.

537,449.—SAVINGS BANK—J. H. Greefkens, S. F.

537,532.—TRUNK—W. C. T. Hausen, Seattle Wash.

537,451.—CONDENSER—W. P. Hawley, Oregou City, Or.

537,704.—ROASTER—N. H. McAuslan, Sutter City, Cal.

537,556.—GOLD-SAVING APPARATUS—A. G. Tingman, Indio, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreigu Pateut Agency, the following are worthy of special mention:

RIVETING MACHINE—John I. Smith, Chico, Butte Co., Cal. No. 534,527. Dated Feb. 19, 1895. The object of this invention is to provide a machine by which rivets and washers are delivered to a point where they are to be used to secure the parts of a helt or other object together. It consists of a table upon which the parts to he riveted are supported, and mechanism for seating the washers upon the parts, mechanism for perforating the hole through the parts from helow and for setting the rivets through the hole aud washer, and a mechanism for heading the rivets after heing set. The washers are contained in a vertically moving bollow receiver and are delivered singly upon the material, where they are held by a trestle foot until the hole is punched through the material hy a punch moving upwardly from helow through an opening in the tahle. A riveting punch is movable within the hollow presser foot so that the point rests upon the upwardly projecting end of the rivet and a hammer suspending above the head of the punch is released to fall upon it at the proper time, so as to upset the rivet and head it upon the washer. The rivets are contained in suitable holders, and a feeding tuhe is provided with a transversely moving slide aud actuating mechanism whereby a rivet is removed from the tube and transferred to the head of a plunger which receives it. After the hole has been punched in the material and the punch heen withdrawn, the plunger is elevated to force the rivet through the hole. Mechanism for operating the parts and producing the various motions consists essentially of reciprocating levers and pedals hy which they are connected and hy whieh they are operated.

RIVETING MACHINE.—Johu I. Smith, Chico, Butte Co., Cal. No. 537,314. Dated April 9, 1895. This invention relates to an apparatus for riveting articles together and automatically supplying rivets and washers, together with punches, one of which is advanced to punch a hole through the material, after which a rivet is forced through the hole and through a washer which has already been placed upon the opposite side of the material, after which a hammer is allowed to fall upon the head of a riveting punch, the lower end of which rests upon the point of the rivet where it projects through the washer. The actuating mechanism consists of a series of levers hy which the various parts are moved at the proper intervals, and these levers are so arranged with relation to a revolving wheel or disk having projecting teeth and spurs thereon that each of the actuatiug levers will he moved in its proper time so that the different movements necessary to complete the riveting will he effected at the proper intervals.

GOLD-SAVING APPARATUS.—B. M. Whitiug, Spokane, Washington. No. 537,257. Dated April 9, 1895. This invention relates to an apparatus which is especially designed to save fine gold found in placer mining, in connection with pulp or tailings and other waste matter. It consists of an inclined tuhe into which the material is fed, having its lower end open for the discharge of the worthless material, a cone-shaped drum fixed concentrically and exterior to it, with its lower surface horizontal and adapted to contain a body of mercury, a tuhe extending through the cone and projecting beyond the lower end, having the projecting end open for the discharge of the coarser material and perforations through which the finer material passes into the cone; means for feeding the material to be acted upon to the interior of the tuhe, whicb is suitably mounted so that it can he rotated for the purpose of gradually advancing the material from one end to the other down the incline, and allowing the finer material to pass through the perforations into the cone. Below the cone is a series of riffles consisting of a bottom having pockets and removable copper plates, over which the finer material and mercury passes after leaving the drum.

RAILWAY STREET AND STATION INDICATOR.—A. B. Murray of San Rafael, and Henry G. Krasky of San Francisco, Cal. No. 537,800. Dated April 9, 1895. This inventiou relates to a device which is adapted to indicate streets or stations and which is fixed within the car so as to he visihle to the occupants thereof. It consists of an indicating mechanism, a spiral disk having protuberances upon the periphery corresponding with the location of the streets or stations, and mechanism actuated hy said protuherances wherehy the indicator is advanced to show the name of the street or station, mechanism connected with the car axle whereby the spiral disk is rotated and advanced upon a stationary shaft, a gear mechanism intermediate between the car axle and the spiral disk, a lug upon the terminal plate of the disk, a lever mechanism which is engaged hy the lug when the disk has reached the end of its travel aud a stop actuated by the mechanism to engage and arrest the driving shaft so as to throw the actuating gears out of engagement and thus allow the car axle and its attachments to continue to revolve without affecting the registering mechanism.

Assessment Notices.

OVERMAN SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Gold Hill, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of April, 1895, an assessment, No. 73, of ten cents (10c.) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, No. 414 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 11th day of June, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. D. EDWARDS, Secretary.
Office—No. 414 California street, San Francisco, California.

H. P. TAYLOR MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Liberty Mining District, Siskiyou county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth day of April, 1895, an assessment of Four (4c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 39 Merchants' Exchange, 431 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirty-first day of May, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on FRIDAY, the twenty-sixth day of July, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. HENRY SMITH, Secretary.
Office: 39 Merchants' Exchange, 431 California St., San Francisco.

A SPECIAL MEETING of the stockholders of the Julia Consolidated Mining Company will be held at the office of the company, room 56, No. 309 Montgomery street, San Francisco, California, on FRIDAY, the 3d day of May, 1895, at the hour of 1 o'clock, for the purpose of considering what disposition shall be made of stock now in the treasury of and belonging to this company, and the transaction of such other business as may come before the meeting. Transfer books will close on Tuesday, April 30th, at 3 o'clock P. M.

J. STADTFELD JR., Secretary.

ALBERT MALTMAN, Practical Metallurgist and Engineer.
SAMUEL C. THOMPSON, A. B. Yale University. E. M. Columbia University.

Maltman & Thompson,

MINING ENGINEERS AND METALLURGISTS,

Owners of Nevada County Reduction Works,

Address: Grass Valley, Nevada County, California.

Inspect and report upon Mineral Properties, Treat Refractory Gold Ores and Concentrates by Chlorination. Furnish Plans for and Superintend Erection of Chlorination Plants. General Analyses of Ores.

Coast Industrial Notes.

The Los Angeles *Record* has imported 10,000 one-cent pieces.

—The Risdon Iron Works sent two Bryan mills to Mexico this week.

California printing ink is a new local industry and ought to be a profitable one.

The Standard Oil Co., which now almost completely controls the coast market, is still advancing prices.

—The Perkins Pump and Engine Co. have the contract for putting in an engine and pump for the Kern Co. asylum.

—C. H. Evans & Co. are building a pumping plant, with a capacity of 15,000 gallons per hour, for Cypress Lawn cemetery.

The Mechanics' Institute trustees are energetically arranging for the exposition of '95, which will be opened August 13th.

—The Directors of the San Joaquin Valley Road have decided to build a steel drawbridge across Mormon channel in Stockton.

The Oregon Central & Eastern Ry. Company has been incorporated at Corvallis, Or., to buy the Oregon Pacific property and operate it

The Watsonville beet sugar factory gives employment to 300 people. Twenty tons of beets are raised on an acre of land, for which the farmers receive $80.

—The advance in the price of beef will cause 4000 cars of cattle to be shipped East from the southwestern New Mexican ranges during the next six weeks.

—The Great Northern has joined the Northern Pacific in a decision not to use the reduced steamship rates from Puget Sound for passing to San Francisco.

—During the first fifteen days of April fourteen colliers arrived in San Francisco from the northern mines. The total of cargoes was 37,000 tons, valued at $296,000.

—An evidence of the good financial standing of the city of Los Angeles was furnished last Wednesday, when $396,000 in bonds were sold to Street, Wyke & Co., of New York, at 4½%.

—The net increase in the earnings of the Great Northern system in 1894, compared with the same six months of 1893, was $313,205.75 and the increase in the tax was $10,481.95.

—There are 347 vessels on the Pacific coast in the lumber trade, including steam and sailing vessels, which range in tonnage from the schooner Mary Etta, 85 tons, to the ship Oriental, 1400 tons.

—The Los Angeles and Santa Monica Electric Railway Company will build a railway between those places. There will be a branch fifteen miles long to Pasadena, another five miles long to Cold Water Canyon.

—The ship Olivebank has sailed from Vancouver, B. C., for South Africa with 2,323,684 feet of rough lumber. Her net tonnage is 2627 tons. She is the largest vessel ever loaded with lumber in British Columbia or on Puget Sound.

—General Manager D. B. Robinson of the Santa Fe denies the report that the Santa Fe will build 150 miles of line to make connection with the proposed railway from San Francisco southward and thus furnish an outlet for the Santa Fe on the coast. He says: "There is every indication, however, that a new road from San Francisco into southern California will be built." Mr. Robinson is of the opinion that the new Santa Fe Company will be in active operation by August 1st.

The Western Iron and Steel Company's rolling mill at Lakeview, Wash., started up this week. It is the only rolling mill on the coast outside of San Francisco, and has a daily capacity of eighty tons of bar iron. The start was made with seventy-five men.

—The Clarke and Cox land, known as the San Juan Grant, lying south of Orange Vale, north of the American river, and east of Rancho del Paso, has been bought by Chicago men for colonization purposes; the work of development is to be commenced at once.

—The Victor, Cal., Reservoir Company has sold its property to the Columbia Colonization Company of Chicago. It is proposed the reservoir will contain when full, to the 1465-foot level, 127,721,404,000 standard gallons of water, sufficient to irrigate 220,000 acres.

The Jones Creek Mill, Mining and Irrigating Company, to manufacture lumber for mining purposes, and for mining, has been incorporated at Crescent City, Cal., by John McLaughlin, Eugene Commerford, Wm. Frost, E. A. Frost and Peter Emetsburg. Capital stock, $80,000.

The *Railway Age* says Washington has nine railway companies who contemplate building 376 miles of road this year: Oregon four companies to build 213 miles, and Montana four companies to build 335 miles. To this may be added the S. F. and S. J. V. R. R., which proposes to build 340 miles in this State.

—The opposition in steamship traffic between here and the Sound is ended. The steamer Farallone has given up the rate war with the P. C. S. S. Co. and will run in future between San Francisco and Yaquina bay. Rates which have been $5 from here to Seattle will be advanced to $20 first class.

—The Ogden company organized to work the guano beds on one of the islands in Great Salt Lake, is making extensive preparations to engage in the business on a large scale. A pier will be constructed at Lake Park, a steamer built and shipments commenced as soon as possible. The company expects to sell 100,000 tons in Utah alone.

—A band of 5000 horses has been ordered slaughtered in eastern Washington and Oregon. The meat is to be canned and shipped to France. An effort will also be made to ship canned horseflesh to Japan. The horses were contracted for at the rate of $5 a head, and those not suitable for canning, it is said, will be treated at the rendering works.

—The recent shipment of a carload of California flowers to the Chicago market for the Easter trade was not an entire success, as a large portion of the carload arrived in a worthless condition. Out of 10,000 calla lilies, less than 4,000 of them were found fit for market. In the shipment there were several thousand date and fan palms and 10,000 marguerites in good condition.

—The Northern Pacific Railroad has begun improvements on the water front at Tacoma, Wash., that will cost $300,000. Local companies will make improvements costing $200,000 more. The railroad will build a solid rock and stone seawall along its water-front property. It will build four freight warehouses, each 40x400, and coal bunkers of 10,000 tons storage capacity, capable of handling 5000 tons per ten hours.

—The Oregon Railway & Navigation Co.'s committees of the collateral trust and consolidated mortgage bonds have agreed upon a plan of reorganization which provides that a general mortgage of $21,500,000 at 4% interest is to be issued, into which the present outstanding obligations are to be funded. The collateral trust bonds are to receive 50% in the new 4% bonds and 65% in new preferred stock. The consolidated bonds are to receive par in the new 4s, 21.9% in cash and 36¹.9% in preferred stock. The stock of the company is to be assessed $8 per share, for which preferred stock at par will be given. Of the new 4s $5,000,000 will be held in the treasury to retire the 6% bonds of 1903 when they mature.

—The London *Iron and Coal Trades Review* says: "The announcement that the order for the 20,000 tons of rails required for the new railway running from San Francisco southward has been captured by an American firm will occasion almost as much surprise on this side of the Atlantic as it has already done on the other. It was generally expected that the competition would be close, but as the freight charges favored the British manufacturer somewhat, it was considered most probable that the order would find its way to this country. The event, however, has proved otherwise."

—The H. C. Shaw Plow Works, at Stockton, have made a new twelve-gang plow, which is probably the largest of its kind ever constructed in this country. It was made especially for George McCouley, of Forest Lake, and is designed to turn over the ground for a width of ten feet. The beam on which the plows are fixed is 22 feet long, and the machine is 28 feet over all, from end to end. It will be drawn by a traction engine of 40-horse power. The levers operating on the plow are respectively 24 and 36 feet long. It is expected that a great many more of these plows will be ordered when the work of this one has been demonstrated. It is the first one of the kind ever made, and is a revelation to Eastern men. Last Saturday A. B. Farquhar, a large manufacturer of agricultural implements, of York, Pennsylvania, inspected the mammoth plow. "Nobody but a Californian," said he, "would construct a plow on such a scale. It is truly wonderful what you people out here can do."

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

PLACER

Amalgamators,

Dredgers,

Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.

Highest possible Gold yield insured.

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.

Crushing, Pulverizing, Concentrating and other machinery also built.

Investigation solicited.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager

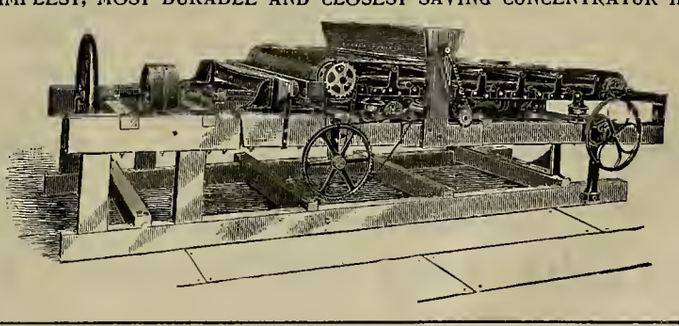
Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness combining both Side and End Motion with a Bumping Belt.
SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.
CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, Igo, Shasta Co., Cal., May 25th, 1895.
THE McGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.
Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I have believed possible for any concentrator to accomplish.
Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 93¾ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.
You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

FRUE ORE CONCENTRATOR,
132 MARKET ST.,
San Francisco, Cal.

GLADSTONE MINING COMPANY, FRENCH GULCH, Shasta Co., Cal.
C. J. Clark, M. E., Gen'l, Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
C. J. CLARK, Gen'l Supt.

IMPROVED CRAWFORD MILL.

The Cheapest and Best Mill for extracting gold from comparatively free milling ores. Requires one-third the water, and three-fourths the power of stamps. Costs less, is operated cheaper, and will save 20 to 40 per cent more gold. Average saving 85 per cent. Inexpensive foundation. No plates or screens. Wear and tear guaranteed not to exceed thirty cents per ton. Capacity ten tons. Full particulars,

MECHANICAL GOLD EXTRACTOR COMPANY,
47 BROADWAY, NEW YORK.

MINING, MILLING AND SMELTING MACHINERY.

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one third the cost in wear of any other crusher in the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

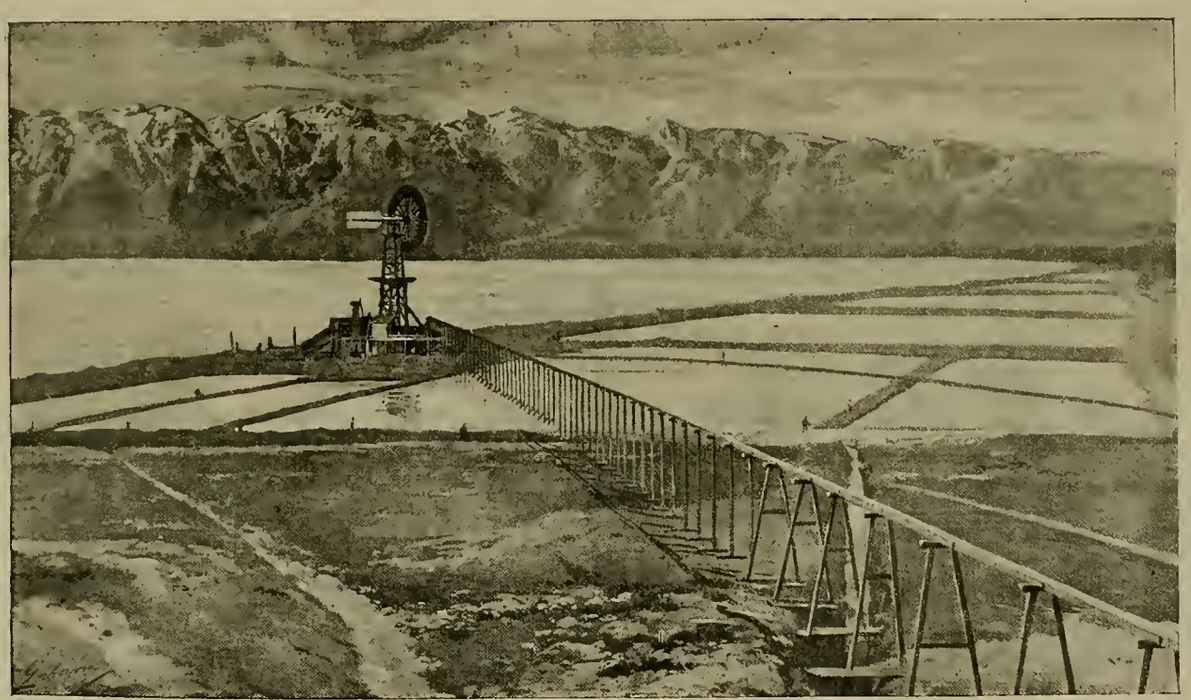
Owens Lake: Carbonate of Soda Manufacture.

California's mineral wealth comprises almost everything that can be classed as mineral, much of which is as yet undeveloped. In Inyo county the Inyo Development Co. many years ago established works for the manufacture of carbonate of soda from the waters of Owens lake, which industry is in operation through the summer months. The accompanying cut gives a very good idea of the lake and the evaporating basins. The works are one mile north of Keeler and are owned in Carson, Nevada.

The lake itself is as unattractive in character as its somber surroundings. In its waters are great quantities of green, slimy vegetable organisms of some low order, one of which forms small globules or spheres about one-fourth of an inch in diameter. There are also several different species of flies which swarm around the lake, and one small species, in particular, which in many places literally blackens the shores with its myriads. There are also in the waters of this lake myriads of small larva, from one-eighth to one-fourth of an inch in length, with many legs and two very black eyes, which somewhat resembles the larva or "wiggler" of the ordinary mosquito, and which are believed to be the larva of the small and multitudinous fly. Each one of these larvæ is inclosed in an almost transparent sack of thin, gelatinous matter. How he makes his way through the water inside of this sack is not known; but he does it, and goes where he pleases. As to the white worms which also exist by millions in this lake, and which by some sort of sticky excretion form sandy cases or coatings for themselves, and which, when washed ashore in masses by the surf, the Indians used to gather, and after drying them and rubbing off their coats, use them for food, it is not known whether they are an intermediate state of the insect between the above-mentioned larva and the fly, or what they are. The fact remains that they exist. Strange as it may seem that a lake, whose waters have the composition which those of Owens lake have, should support life of any kind, it is nevertheless, not only that those waters are full of life, but also that the decay of such life, when washed up on the shores by the surf, and thus left exposed to the sun, often taints the air by its stench for miles around. No ordinary fish can live in Owens lake. There are fish in Owens river, but whenever these find their way down into the lake they quickly die, and are washed ashore.

North of Keeler, on the shore of the lake, are the chief works of the Inyo Development Company, manufacturing carbonate of soda from the waters of the lake. When last visited, for purposes of illustrative description, they had about fifteen acres of ground covered with evaporating vats, made by plowing and then carefully leveling, and afterwards heavily rolling the clayey ground, so as to make it water tight. The water of the lake in July registered 9° Baume, corresponding to a specific gravity of about 1.063. Three months earlier it was 7½° Baume, corresponding to a specific gravity of 1.052. The salts which it contains are chiefly chloride of sodium (common salt) and the monocarbonate, bicarbonate and sulphate of soda.



OWENS LAKE, INYO COUNTY, SHOWING SODA EVAPORATING BASINS.

There is at a low temperature but little difference in the solubility of these salts; at a higher temperature the monocarbonate and the bicarbonate will crystallize out together in the shape of a definite chemical combination with its own form of crystallization, while nearly all the chloride and sulphate yet remain in solution; therefore, their "cold weather soda" is a compound of all the salts, while their "hot weather soda" is a nearly pure combination of the two carbonates with very little of either the sulphate or the chloride.

The crystallization takes place, at a proper temperature, at from 30° to 35° Baume, corresponding to a specific gravity of from 1.245 to 1.299. The substance thus crystallized out at this stage is a definite chemical compound of the two carbonates of soda, which has its own peculiar form of crystallization. This peculiar combination of the two carbonates of soda will only crystallize in this way, in the presence of the chloride and the sulphate, inasmuch as, if it be dissolved in pure water, it cannot then be made to recrystallize in the same form, but will be decomposed, and the monocarbonate and the bicarbonate will then crystallize separately in different forms. On this principle works were erected for the re-solution, recrystallization, and thus the separation of the two carbonates. The water of the lake is lifted twelve feet to the highest vats by a windmill. The mother liquor, containing chiefly the chloride and the sulphate of soda, is returned to the lake.

New discoveries of asbestos or fibrous serpentine in Placer county are of economic importance, indicating the extended possession of this mineral wealth in a wider area in this State than was supposed. California produces the only asbestos in the United States of marketable value, and even that is of meager quantity—never over seventy-five tons annually, worth say $60 per ton. It is not considered of as fine quality as the Italian asbestos, but nearly equal in that regard to the Quebec article, which province furnishes the most of the American market supply. Asbestos mines have been reported in Montana, Wyoming and elsewhere, but the product is, thus far, not a commercial quantity. Its uses are various: fire-proof paint; felt covering for steam pipes and furnaces; packing for pistons and valve stems; curtain cloth, are among the many uses to which this "mineral wool" is applied.

The control of the Sutro tunnel has passed by purchase into the hands of a syndicate composed of European and New York men, who, it is thought, will reorganize matters in such a way as to acquire and work some of the properties it touches. The history of the tunnel from its incipiency to the present time would form one of the most interesting chapters in the annals of Nevada mines. An opportunity, even at this late date, exists to make the enterprise pay well in the light of improved mining processes.

An English chemist named Armstrong asserts it as his belief that no chemical action ever takes place except in the presence of some substance capable of being decomposed by electricity, and that therefore all chemical phenomena are electrical.

The Mexican Exposition will begin April 2, 1896.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Owens Lake, Inyo County, Showing Soda Evaporating Basins, 273.
EDITORIALS.—Owens Lake; Carbonate of Soda Manufacture; Miscellaneous, 273. Freight Rates; Needs Revision; Miscellaneous, 274.
SCIENTIFIC PROGRESS.—The Animal Viewed as an Engine; Science and Gold Extraction; Miscellaneous, 278.
MECHANICAL PROGRESS.—The New Gunboats; The Warship Chicago; Miscellaneous, 279.
ELECTRICAL PROGRESS.—Insulating With Asbestos; Cost of Municipal Electric Lighting; Miscellaneous, 280.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 282-83.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 286.
MISCELLANEOUS.—Concentrates, 275. A Great Mining Empire, and Other Matters; Brickwork Built to Last; South African Gold Mines; The Gold in the Bank ofFrance; Creosoted Telegraph Poles; Tons of Caterpillars; Original and Effective Way of Preventing Strikes; "Pickling" in Foundries; Greenland Glaciers; Cable Railway Over the Niagara Falls; The War Department and the New Small-Bore Rifle, 276. Milling Arizona Ores with a "Colorado" Stamp Mill; Prospector's Horn Spoon; Thought the "Clermont" was Perfect; Paper for Insulation; Paradoxical Things; Eggs in China; Hard Wood Decision; Power From Belts, 277. Mining in Mexico; Single Spindle Edge Moulder No. 1; MacArthur-Forrest Process; Coast Industrial Notes; Personal; Obituary, 278. Patentable and Unpatentable Inventions; A Salt Laker's Description of California Mines, 283. Notices of Recent Patents, 286.

THE National Associatiou of Mauufacturers will hold its secoud annual meetiug in Chicago on the 15th of next October, at which time the Manufacturers and Producers' Association of California will be adequately represented.

THE Governor of California recently wrote to the Governor of Nevada, courteously inviting his co-operation in the matter of securing the meeting of national couventions in San Francisco in '96. He replied discourteously, and the press of the Silver State reproves him for his ungentlemanly action.

RECENT statistics indicate that the number of stamps in present operation in this State about equals the uumber in present operation in the Witwatersrandt district, South Africa—something over 3200 in each case. The daily average of the South African stamps is stated to be four tons, which appears to be an overstatement.

THE *Record-Union* reiterates in its tirades the statement that up to April 1st 112 hydraulic mines have been licensed to operate. The correct number is 86, but neither correctness nor accuracy form any part of the present onslaught. The statement quoted is 76 per cent truth, which is by far the highest percentage of correctness noted in the flood of its statements on this subject. It continues to say a great deal, and if it keeps on may get to believing its assertions itself after a while.

IN response to continued inquiries it is again stated that there has been no suspension of the federal law this year regarding the amount of annual required assessment work on unpatented claims. There was in '93 and '94, but this year the $100 work or improvement must be done. Nor is there the slightest likelihood that the Congress which meets on the 2nd of next December will do anything in the matter, if for no other reason than it would be then too late in the year to make effective any legislation applicable to so wide an area.

THE U. S. Court of Appeals, in this city, last Tuesday decided a case of some interest to miners. D. Hunter, et al., jumped E. L. Preston's placer claim in Flathead Co., Montana, and when suit for ejection was brought, they claimed that his declaratory notice and oath were not made and dated in accordance with the Montana law. A Montana court found for the jumpers. On appeal the court this week reverses the lower court's decision, holdiug that Preston's notice and location were all straight under the mining laws of the U. S. Preston's declaratory notice had a notarial ackuowledgement. The Montana law requires that it be sworn to. This the Court of Appeals holds to be unnecessary.

Freight Rates.

Denver demands railroad freight-rate concessions and in a suit now going on there, instituted by Geo. J. Kindel, the testimony of the freight agents of the Union Pacific, Santa Fe and Southern Pacific systems is of interest to members of the Manufacturers' and Producers' Association of this State. The Colorado shippers want to be put on the same oasis as Chicago in relation to business ou this coast. It is the old question of "long haul" and "short haul," additionally affected by the favorable situatiou of San Francisco with water-route competition, and its geographical and industrial advantage.

The main charge of the Colorado Fuel and Iron Co. is that while an open rate of 60 cents per 100 lbs. on steel rails is allowed from Chicago to San Francisco, the rate from Pueblo is $1.60. The Colorado Iron Works complains that Chicago is also favored on points east and south, and though 1000 miles farther than Denver from El Paso, Texas, yet has a rate within nine cents of that from Denver. The Pueblo company claimed that with fairer adjustment of rates they could have successfully competed for the contract for the 12,000 tons of rails for the San Joaquin Valley Road; but it is a matter of general information that the Pueblo people are in the combine with other rolling mills not to go below certain prices, and that price in Pueblo is $25 per ton, while the Valley Road has a contract for the rails at $26.40 per ton, delivered here.

Some candid statements were made. Mr. Smurr of the Southern Pacific told the Commission on Wednesday of last week that a 50-cent rate from Pueblo to San Francisco on steel rails and fastenings would pay the railroad company the same as a 60-cent rate to this city from Chicago, and that a 33-cent rate on iron pipe and castings carried here would pay as well as a 50-cent rate from Chicago. Chairman Morrison of the Commission said that making rates cheap to this coast would close all the mills in the country, except those on the Atlantic coast. Mr. Smurr said the steamers received 19 70-100ths per cent of the business between New York and San Francisco. In the division of freight between Chicago and San Francisco in the haul of steel rails the Illinois Central receives 24 3-10ths and the Southern Pacific the remainder, or about 33 cents per 100 pounds. Shipments of 2000 tons of rails were recently made on this rate. He said there arrived here from foreign ports around Cape Horn last year 2,740,000 packages of goods which practically came into competition with goods manufactured in the United States. Packages would weigh from 50 to 2000 pounds.

There have been coming to San Francisco from New York by water dry goods, bags and baggings, bats and wadding, furniture, glass, sewing machines, springs, steel, stores, tinplate, tinware, wire netting, hair rope and curled hair, hemp, jute, iron bar, pigs and scraps, lead, pipe, machinery, mats and matting, moss, railroad material, wire goods, cotton yarn, etc.

The railroad carries goods from New York to San Francisco in fourteen days: the Panama route requires about forty days.

Said Mr. Smurr: "Market competition fixes our rates to a large extent. San Francisco is a market for stoves. The stove that can be sold the cheapest and laid down the cheapest is the stove that will be sold in the San Fraucisco market.

"In the case of steel rails they are carried from Pittsburg in clippers at 15 cents per 100 pounds, and from there to San Francisco for 40 cents. To get the haul, the railroads must meet it with a rate of 55 cents."

Regarding the competition on steel rails, Mr. Smurr said: "The rate on rails is 60 cents from New York to San Francisco by rail; by sea about $5 a ton."

The attorney for the Colorado people asked Mr. Smurr if he thought a $1.60 rate from Denver fair as compared with a 60-cent rate from Chicago on the same goods. The reply was: "We say a $1.60 rate from Pueblo to San Francisco is a logical rate. We would like to see the competition of markets enter into the question of rates whenever it can be considered without involving the railroads into observance of the long and short haul between all points."

The whole question of Denver or Chicago or New York entering into competition with San Francisco is of importance only as commeusurate with their natural resources, industrial skill and commercial zeal. Prices and quality of products determine the market.

The discussion now going on in Deuver is of less local importance thau would be one here of Eastbound freights. The question of supremest interest has, so far as we know, not yet been touched on—Shall San Francisco manufacturers about face and move to have this city considered as one of the front doors instead of the back door of the American continent?

Needs Revision.

Mr. Edward Atkinson is our most prominent American statistician. His pleasant though inaccurate style of argument militates against the value of the statistics he so laboriously collates. In the most recent of the many brochures favoring gold monometallism, Mr. Atkinson says:

> In 1860 the unit or standard of value of this country was a dollar made of gold. It had been so since 1834, when, in order to keep silver coin for small change in the country, the standard of silver coinage was reduced from that which had been established by Hamilton at 16 of silver to 1 of gold to 15 to 1.

Mr. Atkinson knows a great many things that are not so. The above is one of them. The fact that the excerpt quoted is exactly opposite to the truth does not tend to augment Mr. A.'s reputation for accuracy.

In 1792 the ratio favored by Alexander Hamilton, after patient research, and fixed by law, was 15 to 1. This was changed in 1834 to 16 to 1, when the law made each eagle contain 232 grains of pure gold, instead of 247½ grains, as by the law of 1792. The gold dollar of 1792 had 24¾ grains of pure gold. In 1834 it was reduced to 23¼ grains of pure gold.

THE contest between the railroad companies and the miners of Montana, similar in the main to the present one of like character in this State, resulted in the last days of the 53d Congress in a victory for the miner, a law being passed authorizing the President to appoint three commissioners to classify the mineral area of that State; this being supplementary to the suspension of issuance of patents to the railway companies for unadjudged mineral lands therein. President Cleveland's appointees are non-residents of Montana. His motives are not to be impugned, but it is a matter of regret that he saw fit to ignore the fact that Montana has many mining men, manifestly more fit to properly discharge the duties of such commission than citizens of Ohio or Indiana. Were the question one of purely agricultural land in either of those States, an Ohio or Indiana man might express some surprise were the President to select a resident of a Montana mining town or a California mine superintendent to constitute the determining body. The matter is one of keen disappointment in Montana. The Governor of that commonwealth writes: "Men destitute of practical knowledge bearing upon the matter of mineral lands, whose ideas have been formed in a school of experience wholly different from the conditions which will surround them as members of a commission to classify these lands, cannot, in the nature of things, deal as intelligently with the question as the interests of the people require. It is the misfortune of those States directly interested in the preservation of their mineral lands that their classification should be delegated to men confessedly ignorant of the nature and scope of the duties they will be called upon to perform." He has selected three Montana men to co-operate (if allowed) with the presidential appointees, and delicately tender some necessary knowledge of the subject in dispute.

REGARDING overproduction, want of consumption, etc., it is remarked:

1. That production, in the grand aggregate, doubles every ten years.

2. That in each decade there is usually a period of about five years in which it declines, or remains practically stationary.

3. That in the succeeding five years it usually leaps forward, till the grand average of ten per cent annual increase is attained.

4. We are in the fifth year of decline from the maximum output of 1890.

Concentrates.

THE Truckee river is higher than for several years.

THE Pilot Bny. B. C., smelter is temporarily closed down.

THE Denver paper mills have daily used six tons of kaolin from Silver Cliff.

IT is believed that the gold output of California for '95 will aggregate $15,000,000.

A 40-STAMP MILL is now running steadily on the Congress mine, near Prescott, Arizona.

A 100-FOOT TUNNEL is being run in the Lupin gravel mine, Washington ridge, Nevada Co.

THERE are 300 more men at work in the coal mines in Belt, Idaho, than there were a year ago.

THE Black Oak mine, near New England Mills, Placer county, is reported bonded for $60,000.

THE United Verde Copper Company gives employment to 300 men at its mines at Jerome, Arizona.

IT is expected that work will shortly be resumed on the Centennial mine, Washington ridge, Nevada Co.

THE Nevada City *Herald* bears that Supt. Howard intends adding ten stamps to the Oak Tree mill at Maybert.

ALEX. BARING has bought the North Pole quartz mine, in Cracker Creek district, Baker Co., Oregon, for $55,000.

HAVILAH, Kern Co., is shipping a carload of antimony ore a month here, where it brings $35 per ton. The ore yields from 45 to 60%.

THE Granite Hill Mining Co., Nevada Co., have rejected the bids for pumping water out of the mine and hired men on day's pay to do it.

THERE are now seventy-eight men at work in the various mines near Silver City, Nevada, and a large number are working individual claims.

THE *Tribune* says Salt Lake smelters are endeavoring to obtain cheaper production methods in order to successfully compete with prevailing conditions.

THE Wadsworth, Nev., *Dispatch* says about every day finds some miner with blankets on his back passing through there en route to Butte City, Montana.

THE new 30-stamp mill at Silver Peak, Nevada, will start up about the 1st prox. There is already enough ore on the dump to keep the mill running several months.

PROSPECTORS are reported "rushing" from all parts of New Mexico and Arizona toward the newly alleged gold find at Carlisle, fifty miles from Lordsburg, New Mexico.

AMALIE mining district has been organized in Kern Co., Cal., at Amalie P. O.; Geo. E. Foster, district recorder. The Occidental Mining Co. is pushing development work.

ADA REHAN in silver, the celebrated statue from Montana, is now on exhibition here in a store on Market street. It is nine feet high, of solid silver, and is valued at $64,800.

THE *Inter-Mountain* says that the men working on the 1000-foot level of the Anaconda mine at Butte, Montana, find their whiskers "changing from their natural color to a pale green."

THE Henrietta quartz mill, near the Alta mines in Owyhee county, Idaho, has been leased to the Alta Gold Mining Co. for the period of one year, and will immediately be put in operation.

THE largest bar of gold bullion ever cast at the Boise, Idaho, assay office weighs 1334.34 ounces, is 937 fine, worth $25,888.15, the product of twenty-three days' run at the Virtue mine, Baker City, Oregon.

THE Lockwood Consolidated Mining and Milling Company has incorporated in this city. Capital stock, $1,000,000. L. Sborcs, T. Fox, R. Feige, K. J. Turner and C. Cleve of San Francisco, directors.

THE Bimetallic Mining Company has incorporated in Oakland. Capital stock, $2,000,000. J. L. Green, A. J. Cabral of San Francisco, J. H. Lucas, J. F. McShain and J. M. Strout of Oakland, directors.

A DEPOSIT of native quicksilver found in the center of the town of Calistoga revives memories of similar finds, which ended indefinitely. The present find occasions considerable prospecting in the vicinity.

THE Gold Bank, at Forbestown, Cal., now has its shaft down 350 feet. A tunnel is being driven to tap the ledge at the depth of 1400 feet. The ledge is eighteen feet in thickness and of a uniform rich character. Ninety men are employed.

THE Odessa Gold Mining Company has incorporated in Sacramento; capital stock, $1,000,000. G. A. Ottmann, H. W. Bragg, J. A. Peck, R. C. Irvine and G. C. Holbrook of that city are directors. They will operate a mine in Shasta county.

THE first gold ever known to have been taken from the middle fork of the Coquille river, Oregon, was brought into Marshfield this week and sold to B. C. Lehmanowsky. It was placer mined from the river bed opposite Enchanted prairie.

THE Denver *Record* says that an Eastern chemist passed through that city a few days ago on route from southern Colorado, where he has been examining a discovery of tin ore. He predicts "a tremendous excitement" as soon as the locality is made public.

THE Lake View Mining Company will start on their mines on the 15th. They are building a twenty-stamp mill. J. W. Moakler is manager. This group of mining claims is in the South Side mining district, thirteen miles from Argenta and twenty-eight miles from Dillon, Montana.

THE 12th report of the State Mineralogist is about out of print. There were 6000 copies printed, but the extraordinary demand has exhausted the supply. The universal interest in the gold mines of the State and the valuable nature of the report occasioned an unusual run on the volume.

IN the Cochiti district, Colorado, smelter returns show a general average of 25 to 35 per cent gold, the balance being silver. Specimen assay samples run high, but the average smelter returns so far, for assorted ores shipped, appears to be from $80 to $100 per ton; ores taken out of all of the principal prospects ranging from $20 to $40 per ton are not being shipped at present.

LAST Monday night the body of John Manahan, fifty-five years of age, who had been missing for two weeks, was found partially submerged in the bottom of the shaft of an abandoned mine on Domarest Hill, near Angels, Calaveras Co. A coroner's jury returned a verdict of accidental death.

E. S. DEGOLYER is developing the Gottschalk mine, near San Andreas; a 3-compartment shaft is down 100 feet, and a crosscut started west. The rock assays $10 to $15. A complete plant will be put in. The owner will return from Salt Lake this week to reside at San Andreas permanently.

THE annual company is being organized to look for a mythical gold ledge found on the Mojave desert many years ago, but lost sight of by reason of the death from heat and thirst of the finder. Considerable money and effort are yearly squandered in this way, but usually the expedition starts a little earlier than May.

D. BONELLI, of Rioville, Nevada, has bonded his mine claims to Salt Lake parties for $10,000, final payments to be made by the first of November next. Four men are at work opening the claims up. They are situated about fifteen miles up the river from Rioville. Sheets of mica six inches square are taken out.

T. PATTERSON, of White Hills, Arizona, has bonded from Phelps and Holmes their interests in the Crescent, Nevada, district for $8000 for three months and have men at work on some of the claims. Part of the money is already paid, and he is said to be negotiating for the purchase of the Legal Tender Co.'s mill.

GOLD RECEIPTS at the Denver branch mint during April reached $241,572.10, compared with $483,242.62 for April, 1894, a decrease of $241,670.52, or fifty per cent. The falling off is accounted for by the entire absence of deposits of gold bars by the smelters, which are being disposed of at a premium to brokers in New York.

THE Nevada *Transcript* says that it cost the shareholders of the Idaho mine $38,549.75 to realize about $12,000,000, which was the total production at the time of its purchase by the Maryland Company. That is an exception to the rule, but there are many other instances of magnificent returns on meager investments.

W. F. KENDRICK, of Denver, writes: "There is a large increase in the tonnage of ore received at the smelters since the dissolution of the Smelters' Clearing House Association, on account of the reduction of both smelting and railroad charges, which encourages the shipping of a lower grade of ores, which can now be sold at a liberal profit."

H. E. PICKETT, manager and part owner of the Grand Victory mine, near Placerville, says, regarding the present litigation, that neither Clark nor Stratton own anything in the mine; that Thompson had some contingent interest with Clark, but that was all extinguished before the present owners took hold of the property.

HIRAM JOHNSON is going to build a mill in Eureka, Nevada, to work the ores of the Silver Comet mine by the cyanide process. Should this prove to be a success the base metal range will be greatly benefited by it, as there are thousands of tons of low-grade ore around there which at the present time cannot be worked to any advantage.

A COMPANY has been incorporated to work a mine of mineral wax near Pleasant Valley Junction, Utah. The wax is contained in small veins and reservoirs in one larger vein. It resembles beeswax in nature, not burning but merely melting down. Genuine oil rock accompanies the wax. Extensive commercial use is expected to be made of the substance.

C. W. AND C. H. JACKSON, of New York City, and A. Case of Boise, Idaho, have bought the Phœnix mine, Robinsonville district, Baker Co., Oregon, for $40,000, one-half to be paid on the 5th prox., the remainder conditional upon the showing made by the mine in a certain time under vigorous development, the cost of which is to be borne by the purchasers.

AT the Taylor mine, four miles from Georgetown, El Dorado Co., the work of timbering keeps a force of men employed. They now have 3000 saw logs on hand, 18 to 40 inches diameter. The milling plant has 40 steel 1000-lb. stamps, which have a 4½-in. drop and a speed of 105 drops per minute. A 13,000-lb. Gates crusher, of 25 tons capacity an hour, is part of the equipment.

A DISPATCH from Aguas Calientes, Mex., says: "One hundred cars loaded with machinery for the new smelter that is being erected here by the Guggenheims, of New York and Philadelphia, have arrived. The smelter will be the largest in the world. The Guggenheims have already purchased $5,000,000 worth of copper ore, which is awaiting the completion of the smelter to be reduced."

PORTER & RICHARDS have an electro-chemical process in the neighborhood of Kernville, Cal., by which they claim to work ore to 90% of its assay value that formerly gave only 22%. At the Big Blue, where 80 stamps ran steadily for five years, the average yield was not over 30% of the assay value, the other 70 being supposed to be in the bed of Kern river. The new process should make that mine a valuable property.

UNDER the State law of March, '93, California mine owners are required to use a uniform code of bell signals in hoisting, and to properly post copies of the rules in their mines. If the rules are not observed or notices not posted the owners are liable for damages for any accidents that may occur in such mine while it is operated contrary to law. The official code, printed on cloth and ready for posting, can be had at this office.

TALKING of Montana the Butte *Review* says that this is going to be a great season for mining operations, more particularly in the line of prospecting and the opening up of new placer and quartz districts. Already the hills are filled with prospectors opening up ground that for many years has been considered worthless. Old mines that have been abandoned for years and placer diggings that were abandoned long ago are again being worked.

THE entire plant of the Double Eagle Mining Company, of Maiden, Montana, was sold at sheriff's sale Thursday to satisfy judgments of three preferred creditors, aggregating about $10,000. The famous Spotted Horse mine, which in its time has been one of the fancy gold producers of Montana, was chief among the properties to be knocked off to the highest bidder, and the celebrated mine, the pride of Fergus county, went for a song, mine and mill bringing $8000.

ACCORDING to the Cripple Creek, Colorado, *Journal*, the leasers of that camp are making mines out of the ground that would otherwise be lying idle did they not take hold and open them up. The companies simply hold the sack and rake in their royalties, ranging from 15% to 25%. Then come the hungry sub-leasers who are anxious to get a mouthful of ground that they may make a living for themselves—and money for the company. They pay from 20% to 35%, and some as high as 40%.

AT the McCabe mine, near Prescott, Arizona, last Saturday, Peter McGlendon, a miner, started with a companion to go from the 350-foot level to the top of the shaft in a cage used for hoisting ore. At the 350-foot level he took a third man on; and in pulling the bell cord to signal the engineer to hoist the cage, the wire rope broke about 200 feet above them and dropped on to the cage, catching McGlendon in its coils, causing him to fall sixty feet to the bottom of the shaft. His neck was broken by the fall. His two companions escaped without injury.

THE deepest gold reef in Australia is the property of the New Chum Railway Gold Mining Company, Bendigo, Victoria. The reef is being worked at the depth of 2,845 ft. from the surface, and a crushing of 197 tons of quartz has yielded 285 ozs. of gold. The temperature in the level is excessively high, the air heavy and oppressive through impurities exhausted from the air-driven rock-drills, and the water which oozes from the face is quite warm. The men at work wear nothing but trousers and boots, and the perspiration streams off their bodies as though they were being hosed down.

PROFESSOR R. H. BLIVEN, who committed suicide at Loomis, Wash., last week, was a thorough assayer, chemist and metallurgist, and had been identified with Okanogan since it became a mining country, being connected with the Black Bear mill and later with the Triune mill. He had for a long time been working upon a chemical process of extracting metals from ore, which was considered practical by many of those who had witnessed the operation. In small tests, twenty minutes was sufficient to liquefy the pulp and precipitate the metals. The knowledge of this process dies with him.

MESSRS. HOOPER, TIBBETTS AND ALLISON are building a ten-stamp quartz mill at the forks of Kern river to be run on Keysville ore. They have the ditch ready to turn water on the wheel and the excavation finished for the mill and the tail-race. This site is on the banks of Rich gulch, out of the reach of the freshets of Kern river. Early miners made many efforts to utilize the waters of Kern river in crushing Keysville rock, but all these efforts came to grief as the result of high water, and of late years most of the gold of that district has been taken out by horse power at an average cost of about $8 per ton in addition to hauling.

THE Mayflower, in Placer Co., paid a dividend of $10,000 in March, a total of $30,000 since Jan. 1st. The Morning Star, in the same county, paid $16,800 that month, $36,000 since Jan. 1st. The Standard, of Bodie, also paid $10,000 in March. The Kennedy mine, of Amador county, has paid $96,000 since Jan. 1st. Others not reported are paying big monthly dividends right along. It is calculated that 148 dividend-paying mines have paid $300,000,000 since '71. It is figured that their gross output for that time was $1,500,000,000 and that $1,200,000,000 was paid out for machinery, supplies, labor, etc. That is, a billion and a half was added to the solid, tangible, permanent wealth of the world, the dividend part being incidental.

AMONG recent Colorado gold mining incorporations are the Minnie Brown Mining Company, an Ohio concern; capital stock, $25,000; A. E. Monett of Sterling, Colo., is local agent; High Line Gold Placer Mining Company, to develop placer claims in Rio Hondo mining district, Taos county; capital, $1,000,000; Maxon Mining Company; capital stock, $10,000; to operate in Boulder county; Mineral Hill Gold Mining and Milling Company; capital stock, $500,000; to operate in Park and Arapahoe counties; Gough Mining Company; capital stock, $100,000; to operate in El Paso county; Midas Mining Company: capital stock, $100,000; to operate in Lake and Arapahoe counties; The Manthald Gold Mining Company; capital stock, $250,000; to operate in Gilpin county; The Erie Gold Mining and Milling Company: capital stock, $100,000; headquarters in Denver.

CONSIDERABLE placer mining will be done in southern Oregon this season. There is some stir in the vicinity of Gold Hill, about fifteen miles from Jacksonville, Jackson Co. The Gold Hill Channel Mining Co. has several claims on Foote creek, two miles from Rogue river, along an ancient river channel which they have tunneled 1500 feet and which turns out "black gold" bringing $18 an ounce at the mint in this city. Ed. Schieffelin, the discoverer of the Tombstone, Arizona, mines, is running a tunnel near Woodville, the ore from which is rich in free gold. He has another claim on California creek, and a five-stamp mill which turns out good returns. F. Laurence, from another adjacent quartz claim, recently sent 11 tons of ore to this city, which brought him $4800, at an alleged expense of $500. It's a good country to mine in, and is attracting the renewed attention of the prospector and the capitalist.

THE daily questions sent to this office often embrace some that make correct answer difficult. The inquiries are answered as quickly and correctly as possible, though accuracy is not always claimed. One came last Tuesday week that is given publicity, contrary to our usual custom. It is: "How many stamps are in preseut operation in California?" From procurable data it is believed that the following would approximate the number: Amador, 245; Butte, 175; Calaveras, 290; El Dorado, 330; Fresno, 40; Inyo, 25; Kern, 35; Lassen, 40; Los Angeles, 25; Madera, 35; Mariposa, 35; Mono, 90; Nevada, 375; Placer, 140; Plumas, 180; Riverside, 90; San Bernardino, 65; San Diego, 75; Shasta, 295; Sierra, 90; Siskiyou, 190; Tulare, 40; Tuolumne, 70; Trinity, 105; Ventura, 20; Yuba, 25. Total, 3125. Exactness is not claimed. If any recent list has been published it has escaped our attention, and any effort to secure the exact number must, obviously, be approximate. If our interior contemporaries, who are severally better acquainted with their localities than any one person can be, will send a completed estimate of the number in operation of which they are cognizant, the PRESS will be pleased to publish it.

A Great Mining Empire, and Other Matters.

To the Editor:—We of California have a great idea of our enterprise in mining. During the bonanza days we showed an aptitude for the pursuit, and during the excitement of the Comstock we had much to be proud of, but when we come to compare all we ever did there, even were we to class the entire Comstock as oue enterprise, and all we have done siuce, the whole falls into insignificance when we stop to review the scope of the British South African Co., which has secured from the English Government a miuing empire larger than all the mining counties of California combined, and in that territory they have discovered and "pegged off" 1890 miles of quartz reefs. This stupendous incorporation, with its $100,000,000 of capital, is capitalizing other companies and placing them on the European market, all formiug a source of revenue that will outvie in time the fabled wealth of Croesus. Out of these 1890 miles of quartz claims there are 380 miles of ancient workings, and it is estimated that millions of pounds of gold have been extracted, judging from the excavations made.

At the present time all Europe is in a miniug fever—a fever, it is said, which has its parallel only in the "South Sea Bubble" and the Tulip craze. But in this African furor there is a substance at its back which the "bubbles" had not, and which has built it up and will carry it on to a greater outcome. This substauce is in the $125,000,000 of gold that has beeu produced iu the past six years, and in the $35,000,000 per annum that is now the outcome of the Witwatersrand alone. The Witwatersrand is entirely foreign to the British South African Co., with its 1890 miles of discovered quartz reefs.

One's imagination can hardly grasp the future of these African gold fields and their effect on the monied centers of the world, particularly so when we consider the question of our perfected mechanical and chemical appliances for the extraction of gold, and also the vast population of the cheapest labor anywhere obtainable which is at hand there.

We in California boast of our gold area and think that we are doing wonders, when in fact we are falliug into the background as a gold-producing State aud in auother year, unless we "brush up," will fall behind Colorado, which has made no pretensions as a gold-producer until within the past five years. From a yearly yield of about $70,000,000 we have fallen off to less than $14,000,000. Of course there is a good cause for the major part of this decline, but when California's gold yield falls below $25,000,000 per annum it is through the action or inaction of her own people. The tirade against hydraulic mining has cost the people of the State a loss of at least $200,000,000 of gold, considering what would have been produced by this class of mining and also in other ventures by the use of this money. In consequence, we have for years been crying "hard times." Is it any wonder when we have cut off one of the great resources of wealth, and which could not be absorbed by railroad tariffs?

The business wealth of California is not in her commerce. We have no great commercial brains. Our grain interest has no future like in the past, as Cauada and India are to supply in the main the English market. Our wine, wool and fruit products are mainly absorbed by railroad greed. What, then, have we to look to for much profit but to work our mines? Our mechanical establishments are comparatively at a standstill and from the simple fact that we allow the East—I may say Chicago—to undersell us, aud deliver the goods in parcels at our very doors. For business, says one, we want more money. Are not our mountains stored up with gold? Why should not the effort be made to take it out? The State has never been so prosperous as when we mined most, and why is not mining the most desirable of all pursuits for California and Nevada? Mining on a scale to correspond with the expanse of our gold fields would soon stop the cry of "no money;" it would cause the fires to be started up in our fouudries, and also give general activity to every branch of trade. The time has come when we should awaken to the fact that while the rest of the world are giving out much of their energy and capital for mining enterprises, Californiaus at least should maintain their past record by doing their part in the opening up of new gold resources, for the good of themselves if not for the world at large. We cry for more money when we have not ouly gold fields, but silver ones as well, seeking the hand of capital, and which would, were it not for the work of selfish bankers, be adding their wealth for the enrichment of mankind. The cry of a lack of parity of the metals is as devoid of force as it is of fact. When we sum up the volume of the two precious metals and give a thought to the output of gold in all the gold-producing countries of the world, we see that unless silver-mining is resumed that metal will soon reach the point of being the one most desirable and useful for business purposes. That there should be a political rebellion on the silver question, every man of figures can see.

The masses, to save themselves from wading in the slough of poverty, must rise and overthrow the force of the banking powers which is arrayed against them. Our upward chances for wealth and comfort are in proportion as we can mine and mint the precious metals, and until this is done in order to get more money, we will have to wade on in our poverty-stricken channels. It is the most simple and comprehensive of business propositions, and why should we not, as intelligent people, act upon it? Europe is even now reviving in monied wealth, drawn from her mines in South Africa, Australia and America, and it devolves upon us as a precious metal-producing country to become enterprising also, by extracting our metallic wealth for use and when this is done we should devise ways for retaining it, which we have been too slack in accomplishing in the past.

Almarin B. Paul.

San Francisco, April 30, '95.

Brickwork Built to Last.

In demolishing a part of the Albert warehouses in Liverpool, belonging to the Mersey Docks and Harbor Board, it occurred to the assistant engineer in charge of the work to make some investigations into the strength of the old brickwork. The wall was built about fifty years ago of hand-made bricks, laid in ground mortar made with Flintshire lime. This lime is in a high degree hydraulic and has a reputation of making mortar of exceptionally good quality. The Journal of the Royal Institute of British Architecture, which describes the investigation, states that the engineer conceived the happy thought of leaving a piece of it in the form of a horizontal beam, having a twelve-foot span and measuring about two feet square in section, seven courses in the height of a two-foot wall. The ends of the beams were not cut free from the rest of the work. This beam was then loaded with all the weight that could be conveniently piled upon it, with no appreciable deflection or other sign of weakness resulting. Two courses were then cut off and the whole weight again put on, but without other result. The beam was further reduced by a course, leaving it four courses, or fourteen inches deep, and the ends were also cut free from the other work—the mortar beds of the twelve-inch bearings being untouched. A centrally placed load of five tons fifteen hundredweight was then gradually piled upon it, and was borne for several days without apparent effect upon the brickwork. Finally the weight was increased to six tons nine hundredweight twenty-three pounds, when the beam collapsed during the night and came down in pieces more like broken timber than anything else. Other tests were made with similarly astonishing results, but the above are sufficient to show what really first-rate brickwork in hydraulic lime will stand.

The gold in the Bank of France increased during 1894 by $71,600,000, and since the 1st of January $16,000,000 more have been added to this, making the total reserve $427,600,000. But the Bank of France does not pay out all its gold on demand, as does the United States Treasury. The ratio in France is 15½ of silver to 1 of gold, and every time that money is demanded of the bank its rule is to pay one-half in gold and one-half in silver. This has not brought France to the silver basis. Both gold and silver are used in the payment of debts. Why should not our Government do what France has successfully accomplished? Our ratio of 16 to 1 ought to be more easily kept at parity than the French ratio. It was the remonetization of silver by the law passed in 1878 that made it possible to resume specie payments in 1879. That resumption in both metals was followed by great prosperity for several years, until, without authority of law, the Secretary of the Treasury made a rule discriminating against silver, and paying debts in gold alone. There would be no trouble in the treasury if the Government should redeem greenbacks or other paper money half in gold and half in silver, as the Bank of France has all the time been doing. That would be also in compliance with the law, as the present practice is not.

Six hundred creosoted telegraph poles to hold wires which pass over the high mountains of Mexico were sent out to Tampico on the British steamship "Benwick," from Philadelphia. The poles were so black with the oil which had been forced through them that they resembled iron in both weight and color. It has been found in Mexico that wood is so rapidly destroyed by tropical birds and insects that it was necessary to inject some poison that would have the double purpose of preserving the wood and preventing the poles from being used for roosting purposes. Copper wires are almost exclusively used, as they have been found to last longer and hold the weight of birds and monkeys, which crowd them at night. Electric Review.

It is reported that thirty-six tons of caterpillars and a large number of cocoons—in all 35,000,000 insects—were destroyed in the effort to drive the pest from the young plantations of trees on Hong Koug Island. They appeared on the pine trees with which the Government is trying to reafforest the island, and lasted for two months. Stations were established where the caterpillars were received aud paid for by weight, and this method appears to have proved as effective as could be desired.

South African Gold Mines.

Prof. Suess, the celebrated Vienna geologist, has compiled data which indicates that the bursting of the South African boom is not remote. He shows that the increased production of those gold fields is deceptive. Whereas the yield of 1894 was thirty-seven per cent above that of 1893, it was obtaiued by the treatment of sixty-three per cent more ore. The following table, giving the yield in pennyweights per ton for twelve of the leadiug mines of the district, shows to what an alarming extent the value of the ore decreases with depth. It must also be remembered that as depth is attained the cost of mining increases:

	1894.	1891.	1890.	1889.
City and Suburban	8	12	15	30
Crown Reef	7¾	10	16½	12
Durban Roodepoort	9½	11¼	18¼	25
Jubilee	10½	16	22	15
Jumpers	8	7¾	6¾	14
Langlaagte Estate	8¼	14	15	22
May Consolidate	6½	9½	14½	20
Robinson	19½	23	30½	52
Salisbury	13½	32	29	37
Simmer and Jack	8½	9	8½	16
Stanhope	9	12	16½	16
Wemmer	10	9	18½	16

In London speculation in South African mining stocks has reached a furor hardly equalled in the century, aud every thinking man knows that the crash cannot be far away. This is to be deplored by the American miner, because while the craze is on nothing can be done with American mining properties in London, and because when the crash comes it will be so terrific that mining will suffer general discredit, and investment will turn to other fields.—Spokane Review.

"They had an original aud effective way of preventing strikes on the Sonora Railroad while it was building," says its first superintendent. "The Mexican peons were queer laborers to deal with, and there were habitual kickers and agitators among them to stir up discontent, like those we find in other more enlightened regions where great works are carried on. The Mexican Government, standing as a backer of the road, was, of course, interested that nothing should interfere with its progress, and so when it was discovered that a man was stirring up trouble among his fellow-laborers, he was disposed of in a way peculiar to the country. Some men were detailed to get him drunk—no difficult task when liquor was furnished free—and he would wake up in the morning to find himself in military barracks, and to be informed that he was an enlisted soldier in the army. All the formalities had duly been gone through with, and he was kept in seclusion in the barracks until he was transferred to some remote part of the Republic. He was enlisted under an assumed name, so that when his friends came to the barracks to inquire after him by name, they were informed that there was no such man there. If they doubted the statement there were the rolls which they might inspect. As the Mexican soldier is virtually a prisoner, and the army is made up to a considerable extent of criminals pardoned under condition of enlisting, no comment would be excited by the keeping a new recruit in confinement, and, off in Yucatan or Tabasco, his friend would not hear of him again, at least during the building of the road."

In foundries it is customary to immerse castings in a bath of dilute sulphuric or nitric acid, in order to remove burnt sand and scale. This process is known as "pickling." The fumes from the acid render this method of cleaning the metal very offensive. Many attempts to use electricity as a substitute have been made, but without success until recently. A plan invented by Dr. A. H. Ramage, of Edinburgh, is now in use in a wire mill near Chicago, aud proves a great success. The objects to be pickled are attached to the anode, or positive pole, which, with the negative pole, is immersed iu a solution of some salt of iron not named. Electrolysis results, and the iron taken off the pickled rods is deposited ou the cathode.

Nearly all the Greenland glaciers and tongues from the internal ice cap terminate in vertical faces from one hundred to one thousand feet high, presenting facilities for investigation. The vertical faces reveal pronounced stratification on the basal ice, even earth materials in the bases carried by the ice being arranged in layers. Fine laminations were seen, twelve to twenty to an inch. The layers are sometimes twisted and contorted, and even "shoved" over each other. The glacier movement at the ice border is a foot per day to a foot per week.

It is proposed to construct a cable railway over the Niagara Falls. Powers have already been acquired from the Canadian authorities, and application has now been made to those of New York. It is intended to erect two steel towers about twenty feet high on each side of the stream and to stretch the cables between them.

The War Department has been obliged to issue a general order warning soldiers against burning their hands in using the new small-bore rifle. The heat generated by firing the smokeless powder is so great as to require caution in handling the piece.

Milling Arizona Gold Ores with a "Colorado" Stamp Mill.

By Willard S. Morse, Prescott, Arizona.

Referring to Mr. Rickard's paper on "The Limitations of the Gold Stamp Mill" (*Trans.*, xxiii. 137), and the discussions that have followed, and without entering into any controversy as to the relative merits of the "California" and "Colorado" types of stamp mills, I wish to give the results obtained on ores from Lynx Creek district, near Prescott, Arizona, with a stamp mill of the Colorado, or, more precisely, the Gilpin county, Colo., type.

The mines of the district have been worked for nearly thirty years, yet in that time, very little, if any, work has been done on the veins below the line where the oxidized or "free" ores end, and the sulphide or "base" ores come in, except in a few cases where the sulphide ore was high enough in value to ship to smelters. The surface or oxidized ores have been worked in arrastras and stamp mills, but few attempts have been made to mill the so-called "base" ores. About thirteen years ago a smelter was built in the district by Mr. John Howell to smelt these ores, but was abandoned on account of the high transportation charges on fuel and bullion.

The saving shown in this paper is not claimed to be high, and the history of the district has been given to show that heretofore, at least, the ores have not been considered suitable for stamp milling.

The ore from which the results are given was extracted from below water line (100 to 250 feet from the surface), and is a quartz carrying zinc-blende, iron pyrites, galena, and a small percentage of copper and arsenical pyrites.

MILL.

The mill is a typical "Gilpin County" stamp mill of ten stamps. No rock-breaker or self-feeders are used, the ore being fed by hand. I do not wish to be understood as advocating this method of feeding. It was adopted as a method of economy in first cost of plant, as the attempt to mill these ores was regarded as an experiment, in view of the history of the district.

The weight of stamps when new was as follows:

	Pounds.
Stem	265
Tappet	35
Head	225
Shoe	85
Total	610

The stamps dropped 15 inches, 36 times per minute, in the following order: 1 5 2 4 3.

The mortars are provided with copper amalgamating plates, the front plate being five inches and the back plate ten inches wide. Both plates extend the full length of the mortar, and have an inclination of 45°.

The outside plates (one for each battery of five stamps) are 96 by 52 inches, silver-plated (one ounce to the square foot). These plates are set with an inclination of 1⅝ inches to the foot.

CONCENTRATORS.

For concentration of the tailings after amalgamation, two Gilpin county bumping or percussion tables are used. The beds of these tables are made of cast iron. The cam-shaft of the table is run at 78 revolutions per minute, giving the table 156 strokes or bumps per minute.

CALCULATIONS.

The calculations presented are based on the following data:

Tailings.—A sample of the tailings running from the mill is taken every half-hour by diverting the entire stream of tailings through a swinging trough, which discharges into a galvanized iron tub. This trough is operated by a cord from the battery. The sample thus collected, containing the proper proportion of slimes and sands, is decanted after completely settling and evaporated to dryness. Two such samples are made daily and assayed, and the results given below are the average of 503 samples and assays.

Concentrates.—The weights, assays and analyses of concentrates given are from smelter returns.

Bullion.—United States mint returns are used for contents of bullion.

Ore.—The assay value of ore has been determined by calculation based on the weight of ore and concentrates and the contents of bullion, concentrates and tailings.

RESULTS.

The following are the results obtained from the milling of 2432.9 tons of ore of an average assay value of 0.763 ounce of gold per ton, which varied in a monthly run from 0.574 to 1.18 ounces per ton.

Amalgam. — Total amalgam recovered, 5711.6 ounces. Of this, 70.2 per cent was from inside battery plates, and 29.8 per cent from outside plates.

Retort.—Weight of retort, 2024.45 ounces, or 35.4 per cent of weight of amalgam.

Bullion.—Weight of bar, 1854.38 ounces. Loss of weight in melting retort, 8.4 per cent. Assay of bullion, gold, .636 fine. Contents of bullion, gold, 1180.148 ounces.

Concentrates.—Net weight of concentrates, 605,149 pounds avoirdupois, or 12.4 per cent of weight of ore. Assay and analysis of concentrates, Au, 1.347 ounces per ton; Ag, 6.93 ounces per ton; Pb, 6.34 per cent; SiO_2, 9.9 per cent; Fe, 30 per cent; Zn, 6.85 per cent. Contents of concentrates, 407.6972 ounces of gold.

Tailings.—Weight of ore, 4,865,822 pounds; weight of concentrates, 605,149 pounds; weight of tailings, 4,260,673 pounds. Assay of tailings: Average of 503 samples and assays, 0.1271 ounces of gold per ton. Contents of tailings, 270.8327 ounces of gold.

CALCULATION OF SAVING AND LOSS.

	Ozs. Gold	Per Ct.
Bullion	1180.1480	63.5
Concentrates	407.6972	21.9
Tailings	270.8327	14.6
	1858.6779	100.0

The highest results obtained by amalgamation was on a lot of 332 tons, assay value of ore 1.134 ounces per ton, which was:

	Per Cent
By amalgamation	76.3
In concentrates	14.1
Lost in tailings	9.6

SIZING OF TAILINGS AND CONCENTRATES.

Mesh of screen used on battery.	Material.	Coarser than 60-mesh, per cent.	Through 60-mesh and remaining on 80-mesh, per cent.	Through 80-mesh and remaining on 100-mesh, per ct.	Through 100-mesh and remaining on 150-mesh, per ct.	Through 150-mesh and remaining on 200-mesh, per ct.	Finer than 200-mesh, per cent.
30	Tailings	5.4	3.9	15.6	12.3	11.	51.8
30	Concentrates	2.8	2.4	7.8	16.	19.4	51.6
40	Tailings	6.6	5.	10.8	13.6	6.8	57.2
40	Concentrates	1.9	1.1	5.9	16.5	22.1	52.5
60	Tailings		2.	3.	14.5	9.5	66.
60	Concentrates		2.	3.5	10.4	30.	58.2

Tests made by panning weighed quantities of tailings and weighing and assaying the concentrates thus recovered, showed that about 60 per cent of the gold lost in tailings could be accounted for in this way. The concentrates thus saved, however, invariably assayed much lower than the average of the concentrates that were saved on the concentrating tables, and were very fine, 90 per cent passing through a 200-mesh screen.

Sized samples of concentrates, each size assayed separately, invariably show that the finer concentrates assay less than the coarser sizes.

The following results on a sample of concentrates assaying 1.8 ounces of gold per ton will serve as an illustration of one of many such experiments that have been made:

SIZE AND ASSAY OF CONCENTRATES.

Size—	Assay.
Coarser than 60-mesh	Ounces gold per ton— 2.6
Through 60-mesh, remaining on 100-mesh	2.2
Through 100-mesh, remaining on 150-mesh	2.2
Through 150-mesh, remaining on 200-mesh	2.
Finer than 200-mesh	1.5

CONCLUSIONS.

From more than eighty assays made on specimens of the various characters of ore found in the district, the following conclusions have been arrived at:

1. That the gold is contained in the quartz and "free," or else is associated with the iron, copper or arsenical pyrites, and that a large percentage of that, associated with pyrites, can be extracted by amalgamation with very fine crushing.

2. That the zinc-blende, as a rule, carries very little gold value, and that in cases where any considerable quantity of gold has been found in the blende, it was very "free," and easily extracted by amalgamation after fine crushing.

3. That the galena, as a rule, assays low in gold and high in silver.

NOTES.

Screens.—Forty-mesh burr-slot screens are used as a rule, and last about three weeks.

Shoes and Dies.—Cast-iron shoes and dies are used, and the actual wear of iron per ton of ore is: for shoes, 1.122 pounds; for dies, 0.692 pound.

Crushing Rate.—The average crushing rate of the mill for nine months, based on actual running time, is 3355 pounds per stamp per twenty-four hours.

Water Used in Battery.—Water used in the battery, 21,000 gallons per twenty-four hours, or 1252 gallons per ton of ore crushed.

RESULTS ON ORE HIGH IN ZINC.

The results on a small lot of ore selected for high zinc contents may be of interest.

The assay and analysis of the ore are calculated from contents and analysis of concentrates and tailings, weight of ore and concentrates and contents of bullion.

Ore.—Assay value of ore, 1.393 ounces of gold per ton. Analysis, Pb, 2.90; SiO_2, 59.0; Fe, 8.8.; Zn, 9.7 per cent.

Amalgamation.—The ore yielded by amalgamation 0.9 ounce fine gold per ton.

Concentrates.—One ton of concentrates was made to 3.8 tons of ore. Assay and analysis of concentrates: Gold, 1.54 ounces; Pb, 7.4; SiO_2, 9.8; Fe, 21.6; Zn, 19 per cent.

Tailings.—Assay and analysis of tailings: Gold, 0.12 ounce; Pb, 1.3; SiO_2, 76.6; Fe, 4.3; Zu, 6.5 per cent.

From the above data the following calculation is made:

	Contained in Bullion.	Contained in Concentrates.	Contained in Tailings.
Gold, per cent.	64.5	29.1	6.4
Lead		67.	33.
Zinc		51.	49.
Iron		64.2	35.8
Silica		4.4	95.6

* Read at the Florida meeting of the American Institute of Mining Engineers, March, 1895.

Prospector's Horn Spoon.

The Grafton correspondent of the Chloride, New Mexico, *Black Range* says:

"Dick White, who is an old California gulch miner, has been showing the prospectors and miners here how to make a great horn spoon with which to test pulverized gold ore or placer gravel and sand. The spoon Mr. White made was an extra good one and was manufactured after the following manner: A large horn is taken, boiled, shaved to an even thickness, the tip cut off, as it is useless, split and then screwed or nailed while it is hot and yielding over a wooden form or mold and allowed to cool and dry for a day or two, and then taken off the mold and scraped or sand-papered and polished on the inside. The prospector or miner then has a light and portable instrument in which to test pulverized ore or placer dirt, which will hold about a quarter of a pan. Dick says the best great horn spoons, or in fact any horn spoons, great or small, can be made from the horn of the male bison, commonly known as the buffalo; or, in case a bison horn cannot be obtained, the blackest horn of a bull or ox which can be got is the next best. The black bison horn shows up the yellow gold by contrast best, and takes the highest polish."

Thought the "Clermont" Was Perfect.

Peter Cooper was one of the invited guests of Robert Fulton on board the "Clermont" when, on her trial trip, she first ploughed the waters of the Hudson by steam—waters which have since been and are now thronged with what are among the most splendid steamboats in the world. Cooper used to tell a story to the effect that there were refreshments and speeches on board; and one of the speakers, after referring in very appreciative terms to the boat, said that, fine and magnificent as she was (she was 133 feet long, 16½ wide, flat-bottomed, straight-sided and with full bows, decked only at the ends and with boilers and machinery exposed amidships), she was probably only the germ of practical steam navigation, and that much finer and faster boats would certainly follow her. At this point Fulton called upon the speaker to sit down, telling him bluntly that he knew nothing of what he was talking about.—American Machinist.

Paper possesses excellent insulation properties, and is therefore available for the manufacture of electric cables and similar articles, says an exchange. During the past several years paper has been used quite extensively in connection with the making up of telephonic cables. Rubber, which is generally employed, is expensive. For instance, the cost of a foot of rubber-insulated cable, such as is needed for ordinary purposes, is about $3.25, whereas the paper-insulated cable, of equal build and effectiveness, can be had for less than $1 per foot. Engineers have put the paper-insulated cables through severe tests with results quite satisfactory.

One of the paradoxical things about people is that they always think times will be better if prices are high, and yet every mother's son and daughter laments bitterly whenever that prayed for advance results in their getting less for their dollar than they got before. They do not seem to be quite sure whether it is prices or things they want in this life. A little study in economics would show them that the ideal condition to be sought is that in which they will get the most things with the least effort. The progress of wages is not alone in increasing the number of dollars, but in enhancing the purchasing power of the dollars they get now.

They do not think anything of an egg in China, it seems, until it is about one hundred years of age, old eggs being worth as much in that country as old wine is elsewhere. They have a way of burying the eggs, and it takes about thirty days to render a pickled egg fit to eat. Some of the old eggs have become as black as ink, and one of the favorite Chinese dishes for invalids is made up of eggs, which are preserved in jars of red clay and salt water, consequently there is not much pleasure in being an invalid in China until you have had plenty of training.

According to a recent legal decision reported in the *Timberman*, hard wood is "any tree that has a leaf as distinguished from a needle." A man contracted to deliver to a railroad hardwood cordwood, and he delivered poplar in part fulfillment of the contract. The railroad rejected this as not hardwood, and sued, but the contractor won the case on the decision of the court.

The Chinese divide the day into twelve parts of two hours. The Italians reckon twenty-four hours round, instead of two divisions of twelve hours each, as we do.

To obtain a greater amount of power from belts, the pulleys may be covered with leather. This will allow the belts to be run very slack, and give more durability.

The MacArthur-Forrest Process.

SAN FRANCISCO, April 29, 1895.

TO THE EDITOR:—You will observe, in the judgment rendered by the Appeal Court in London, that the judges decided that "the selective action claimed by the plaintiffs and the application of a very dilute solution, containing an extremely small quantity of cyanide of potassium, to ore containing gold, has, in our judgment, been proved." Now this very dilute solution (never exceeding two per cent of cyanide of potassium) is one of the special and distinctive claims of the American patent; therefore, had the trial taken place in this country upon the American patents, our company would have won their case, and this decision is a most important one, in view of the suit now pending with the Mercur Company and others.

Therefore I would ask you to kindly insert this letter in your valuable journal that it may be generally known throughout the country.

Faithfully yours,

THE GOLD & SILVER EXTRACTING CO. OF AMERICA, L'D,
Per P. GEORGE GOW, Agent.

The Denver *Republican* says that cyanide promises to become a prominent factor there; and the erection of plants in many parts of the State to employ it in the separation of gold from the quartz means much for the mining industry of Colorado. Two large plants are nearing completion at Florence, there is one in operation at Cripple Creek, one has been running for several months in Boulder county, and another will be completed in that section in a few days.

"The formation of a company to build a plant in Leadville by men who have heretofore adhered closely to the smelting business is one of the signs of the times which cannot escape notice. Edward Eddy, James B. Grant, W. H. James, Guy C. Barton and E. W. Nash of the Omaha and Grant Smelting Company, in association with John F. Campion, A. A. Blow, T. W. Goad, have incorporated to build at once a plant to handle 100 tons of the oxide ores of Leadville a day, and with the intention of increasing the works later to a daily capacity of 300 tons. Mr. Eddy is president and Mr. Grant vice-president of the company. The capital stock is $100,000.

"The same gentlemen in their contract with the MacArthur-Forrest Company, for the use of its patents, have secured the right to establish plants elsewhere at their discretion, which practically gives them control of the entire United States rights of the cyanide process owned by that company.

"One of the directors of the company estimates that fully one-fourth of the gold being produced in the world to-day comes from cyanide plants. There are many large works in South Africa using the process, and one of them is taking out nearly 60,000 ounces of gold a month. So far in Colorado the production has been small; but the completion of the works, now in course of construction, should add largely to the output of the State and from ores that cannot be profitably mined and milled by the more expensive methods. The cost of treatment by cyanide ranges from $2 to $4 a ton. The chemicals cost about $1 to the ton of ore treated."

Mining in Mexico.

H. F. Collins, who has been in Mexico for about six years, engaged chiefly in copper mining and smelting, tells the London *Mining World* what he thinks of Mexican mining in general and of its English record in particular. He says Mexico has not had a fair chance. English companies have been unfortunate in getting hold of wrong properties, or in trying to work them with insufficient capital.

The Americans are getting the cream of the mines. They are more judicious in their selection, and are not afraid to spend money when they have made up their minds that they have a good thing. The English have not employed the right sort of men to select and work their properties. The right sort of man would be one who knows Mexico in the first place, who is accustomed to work there in the second, and who is thoroughly familiar with Spanish. He must also know the local conditions, which very often go to make all the difference between a grand success and an awful failure. The men sent out are frequently ignorant upon all or most of these points. Often mere office men have been sent to take charge of great businesses, and when they come to grief their employers have expressed surprise; but those who have seen them on the spot would have been surprised had it turned out the other way. At other times the English companies have sent out men capable enough in their own way, but absolutely ignorant of the country and of the language; and everybody knows how unsatisfactory it is to manage a property through an interpreter. Then, again, the wrong process of treating the ore has been adopted. Amalgamation and lixiviation processes have been adopted for ores which ought to have been treated by smelting, with the result that a large proportion of the precious contents is lost, and what has been recovered has only been at a prohibitive cost. Water is generally scarce, and that is why amalgamation and lixiviation processes have often been comparative failures. Natural fuel, also, is rather scarce, but the extension of railways throughout the country is rendering it easier every day to introduce coke, which is the best fuel for the purpose.

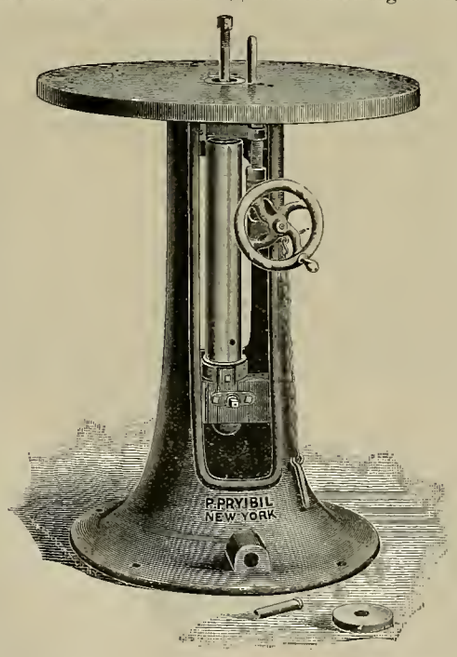
The price of silver does not affect Mexican mining, except as regards the payment of salaries on a gold basis to the English employes; the purchase of materials and plant in a gold-using country, such as England and America, and in the remittance of profits. As regards all the rest of the working expenses—labor and local materials—it does not matter, as you pay in silver, and there is free coinage of silver. Your produce is turned into dollars, and the dollar is the dollar's worth. This amounts to a large premium on silver mining in Mexico, as against silver mining in gold-using countries like the United States and Australia. Therefore, given two deposits of equal richness in Mexico and Australia, the Mexican deposit has an enormous advantage, and profits can be paid where, in Australia, expenses would hardly be met. These are points not commonly understood by English investors. True gold ores are comparatively rare.

If foreigners expect to do their work in an overbearing way they have difficulties with the authorities, but if they are content to act courteously and to conform to the usages of the country, no difficulty will be found. It is quite the exception for bribes to be given. If you go to the courts with a just case and with a respectful demeanor, you will get satisfied. Even if you are defeated in the local courts you can get the matter readjusted at the superior ones. There are no exactions put upon foreigners, for the desire of the Government is to introduce more capital. Mexico is in a fairly satisfactory condition from the mining point of view, but few good mines are in English hands. The Americans have been more successful, particularly in the State of Chihuahua, in the north. Perhaps this is the richest of all the States, and it is being opened up almost exclusively by American capital, and with good results. Still, there are many rich silver properties lying idle for want of capital.

The ores are not refractory to modern smelting processes, but they were so to old Mexican milling. As to labor, in the north it is unreliable and not always easy to get; but in the south it is more plentiful and the men work better. They get a lower rate of wages, and the work they do also is of a low standard. Relatively, labor is not so cheap as would appear from the very low rate of wages.

Single Spindle Edge Moulder No. 1.

Herewith is illustrated a small reverse-motion machine, with a circular iron table thirty inches in diameter and a circular iron body. The spindle is in the middle of table and body, and is of steel, resting on a steel step in an oil well. The bearings are long and self-oiling, each cap being provided with an oil chamber filled from the top, and containing a wick



in contact with the spindle, and extending nearly the whole length of the bearing. Each cap being adjustable by a single central screw, can be brought to a uniform bearing with the greatest ease. The bearings are connected by a frame with which they are cast in one piece, and by which they are maintained perfectly in line. This frame, together with the spindles and bearings, can be raised or lowered by a hand-wheel placed just below the front of the table. A counter-shaft with self-oiling tight and loose pulleys, a belt-shifter, a wrench, two reducing rings for hole in table and three sets of collars for spindle are furnished with each machine.

Parke & Lacy of this city are the coast agents.

Coast Industrial Notes.

—The Scow Bay Foundry, at Astoria, Oregon, has resumed after a long idleness.

—The Sacramento trustees are still playing with the bids for the proposed pumps.

—Wells, Russell & Co. have this week sent nine wooden tanks to the Harqua Hala mine—six 20 feet in diameter and three 15.

—The Southern Pacific Co. has made a rate of ninety cents per 100 pounds on canned salmon from Astoria, Or., to New York and common Eastern points, via the Sunset route.

—The whaleback City of Everett makes the round trip between San Francisco and Comox, B. C., a distance of 1800 miles, in less than nine days. She carries 5000 tons of coal.

—From St. Paul, Minn., comes the story that the Great Northern and the Northern Pacific Railroad Companies are to be consolidated under the management of Jim Hill of the former.

—A cedar tree 407 feet high and seventy feet in circumference was recently felled near Ocosta, Wash. The first limb started sixty feet from the base and was seven feet in diameter.

—The Risdon Iron Works has an order for a 16x42 engine from the Merced Gold Mining Syndicate, of Coulterville. The engine is of the latest pattern and equipped with steam brakes and steam clutches.

—When the Coast and Geodetic steamer Hassler was up for sale on the Sound last week Captain John Irving, of Victoria, B. C., made the highest bid, $5250. The Government has refused the bid on the ground that Irving is an alien.

—Receiver Oakes of the Northern Pacific R. R. says that the shortage in the accounts of the late Paul Schulze, who committed suicide a short time ago after being removed as land agent of the company, will reach somewhere between $100,000 and $250,000.

—A company has been organized at Fresno to put in a telephone system in opposition to the Pacific Telephone and Telegraph Company. It is proposed to reduce the charge to $2.50 a month and use the system now being introduced in San Jose, Santa Cruz and Stockton.

—The Pacific Mail Steamship Company has received a renewal of the contract with the Costa Rica Government to carry mail. The contract is for an annual subsidy of $12,000 (Costa Rica currency) from March 14, 1895, to April 8, 1898. The steamers will touch at Punta Arenas three times a month going north and south.

—The Interstate Commerce Commission has granted railroads terminating in California, and their connections, authority to make a lower rate on oranges to the Atlantic seaboard cities than to intermediate points, enabling California growers to market their oranges on the seaboard in competition with imported oranges. The old rate was ninety cents, the new sixty.

—The Rio Verde, Arizona, Canal Company will utilize the water power of their canal, now being completed, for the generation of electric current. There will be four power stations along the canal line, capable of furnishing, at an ordinary flow, 7000-horse power. The first power house will be built about three miles from the Union mine, nearly eighteen miles north of Phœnix, and will alone supply 4000-horse power, the water of the canal falling forty-seven feet there.

—The Alameda and San Joaquin Railroad Company have incorporated to construct and operate a road thirty miles long in Alameda, San Joaquin and Contra Costa counties. The proposed road begins near the coal mines of the San Francisco and San Joaquin Coal Company in Alameda county and runs to a point on the San Joaquin river and near the dividing line between San Joaquin and Contra Costa counties. The directors are: J. Treadwell, R. I. Fry, E. B. Pond, J. D. Brown, B. M. Bradford. Capital stock, $500,000; $30,000 subscribed.

—The machinery and plant for the fish-oil and fertilizer works, established near Pillar Rock, Washington, are in operation. The process is the same as is used by the Preston Fertilizer Company of Brooklyn, New York, which has the largest oil and fertilizer works in the country. The right of this process for Oregon and Washington has been secured, the plant costs $25,000, and has a capacity of sixty tons of offal per day. The offal will be daily gathered up from twenty of the principal canneries on the Columbia river, and during the season will amount to about 4000 tons.

—The Pelton Water Wheel Co. report a good deal of activity in their business, their orders covering a wide range of country. Among their recent shipments may be mentioned a 200-H. P. wheel for the electric light station at Kyoto City, Japan; a 700-H. P. wheel plant for an electric station in Guatamala; a 1000-H. P. plant for an electric station in Brazil; three wheels for the Majores mines in Mexico; five wheels for the new Hayward & Lane mill in Alaska; one wheel for the Ben Lomond mill in Santa Cruz county; two wheels for the South Yuba Water Company; also a Gates crusher for the Golden Cross mine, of a capacity of 900 tons per day.

Personal.

LOUIS JANIN is examining the War Eagle and other mines at Trail Creek, B. C.

B. J. VIVIAN has been appointed foreman of the West Harmony mine, Nevada Co., vice A. Ohmert, resigned.

W. WESTON, M. E., is warmly endorsed by the Colorado press for the position of State Commissioner of Mines of Colorado.

W. C. RALSTON, secretary of the California Miners' Association, has returned from Europe and is now in Washington, D. C., aiding in the work of protecting the mineral area of the State from railroad absorption.

HARRY WEBB left this week for South Africa to go on the metallurgical staff of the British South Africa Co. It is stated that he will receive a salary of $15,000 a year. Mr. Webb is a graduate of the mining school of the State University.

REV. DR. WILLIAM H. FURNESS, who eighty-three years ago witnessed the launching of the United States frigate Constitution, one of the first war vessels built for the United States Navy for the War of 1812, was an interesting figure at the recent launching of the St. Paul at Philadelphia.

Obituary.

FRANZ POSEPNY, the distinguished Viennese mineralogist, died at Bergrath, Austria, on March 27th, in his 60th year. Readers of the PRESS will recall his recent fine treatise on the "Genesis of Ore Deposits," which elicited deserved praise in this country and Europe.

MAJ.-GEN. JNO. NEWTON died at New York in his 73rd year last Wednesday. As a military leader he distinguished himself on the field of battle; as a civil engineer his name is crowned with success. He commanded the First Army Corps at Gettyshurg, and as commander of the Fourth marched with Sherman to the sea. He successfully solved the problems connected with the adequate improvement of the harbor of New York, and in many difficult engineering matters his advice and co-operation were often sought.

Scientific Progress.

Science and Gold Extraction.

There is an idea prevalent that technical science is rapidly bringing processes of gold extraction to such perfection that almost the ultimate portion of value can be obtained by methods as rapid as they are ingenious. The suggestion is frequently made by writers in the press that a mining district, a chamber of commerce, a State or even a National Government, should offer a large reward for the discovery of a new process suitable to the treatment of complex ores. It is hoped that some heaven-sent revelation will be vouchsafed to some dreaming metallurgist which will revolutionize all pre-existing methods and get 100 per cent of the value contained in the poorest and most perverse of gold-bearing material. Such ideas, such dreams, are all opposed to experience and contradictory to the teachings of the pages which tell the progress of metallurgical art. Evolution, and not revolution, is the keynote of technical science, as it is the clue to physiological development. Processes are born every day, but their mortality is depressing. The examination of the history of the standard methods of ore reduction indicates very clearly that it is in the gradual improvement and extension of established processes and in their adaptation to varying conditions that there will be found the readiest and and safest road to excellence of metallurgical treatment. The cyanide process, for instance, has been the subject of chemical investigation and practical application for six years, and it is yet an imperfectly understood and only a partially successful method Chloriuation was introduced in California in 1856; it has undergone gradual improvement during forty years, but it is still spoken of as a young method of ore reduction. — T. A. Rickard in North American Review.

The Animal Viewed as an Engine.

One of the greatest problems to which the attention of modern experts in mechanical engineering has been directed is this: How shall a larger proportion of the energy known to be stored in fuel be obtained for industrial purposes? Enormous waste attends every process of conversion into mechanical power yet tried. The problem has been attacked on a new side and in an interesting manner by Professor R. H. Thurston, of Cornell University, one of the highest American authorities in this department of science. In animals and man we see substances containing very much the same chemical elements as coal taken into the system, subjected to processes resembling combustion, and finally imparting strength wherewith a certain amount of work is done. Careful investigation shows that the best steam engines show an efficiency of only 20 per cent; that is to say, the actual work performed by them under the most favorable circumstances is just that fraction of the possible power represented by the heat which is taken into the water from the furnace. But in the human machine about 23½ per cent of the energy latent in the average food supply is realized in the day's work of an active laboring man. The internal operation of the system, circulating the blood, pumping air into and out of the lungs, and performing other labors, may perhaps double this estimate. Professor Thurston says, while if the output of nerve and brain power be included in the calculation, perhaps the total efficiency would be between 50 and 60 per cent. This is nearly three times the best showing of a steam motor. The mysteries involved in this superiority, therefore, may well tempt the keenest and ablest engineers more strongly than the physiologist to further investigation.

There are recognized in the arts only three methods of developing mechanical power—by heat, by electricity and by chemical action. Professor Thurston shows at great length that the vital machine is not a heat motor. Upon this point he has no doubt. Though instructions are sent through the nerves of a highly organized animal to its muscles by what seems to be an electric current, this latter performs but an insignificant amount of physical labor. And in man and the horse, for instance, there are no special organs for the production of electricity as in the electric eel. Hence it seems highly unlikely than the animal is an electro-dynamic machine. But its similarity to a chemico-dynamic motor is obvious. In the particular muscle or organ which is telegraphically directed to do something, fats and glucose which have been stored therein are transformed into carbonic acid gas and water. The phenomenon is akin to the firing of an explosive in a distant mine with an electric current. The power in every case seems to be manufactured on the spot, and not to be transmitted from a central station. Each organ and cell, then, is a motor by itself. Further evidence that the nerve-impulse may be electric is found in the fact that a real electric current can be made to produce an identical effect upon the muscles. Nerve energy, like brain power, is subject to exhaustion, and appears to be derived in some way from the daily food, although its source and the method of its development cannot be detected. But inquiry on that point, fascinating and important as it must be to the biologist, the physician and every promoter of the highest civilization, is not likely to yield results of such practical value as the solution of another problem: Is the transformation of fats and starches into carbon di-oxide and water, which accompanies muscular action, a direct or indirect change? If this secret could be revealed and applied to industrial uses successfully, a tremendous revolution would be wrought in mechanical engineering.

One of the most remarkable of recent inventions is a process for making caustic potash and soda out of brine. It has been discovered that these alkalies may be obtained by decomposing brine by means of electricity. The brine is got from salt wells. Sea water would serve, but it is not so good for the purpose because it contains much less salt. Already the manufacture of caustic potash and soda has been begun in Michigan and elsewhere. The matter is exciting great attention abroad, and all the leading chemists of the world are working at it. The inventor of this process is a Belgian named Hermite. In Europe engineers are undertaking to disinfect cities by the use of this process. All that is needed is to run wires from a dynamo into a vessel of sea water, and the latter yields a product which is the same thing as what is commonly known as "bleaching soda." The stuff is so cheaply obtained that it is being used to purify sewers and is poured into gutters. Eventually it will be extensively employed in the sprinkling of streets. By this means of wholesale disinfection, which signifies the destruction of disease-producing germs, cities will be rendered much more healthy in future.

For the past forty or fifty years the geographers and astronomers have suspected that, on account of a "tilting" in the earth's axis, the latitude of all places on the earth's surface is gradually changing. A few years ago (1892) the astronomers decided to make a "test case" of the matter, and now report that the theory is correct. For example, they have proven that Berlin was fifty-one feet nearer the pole in September, 1892, than it was in March of the same year. If Peary and Wellman will only be patient, the pole will come to them.

It is suggested that sounds too high for our ears would be recorded by the phonograph, and might be made audible by reproducing at a lower speed of the instrument.

The new photograph of the heavens, now being prepared by London, Berlin and Parisian astronomers, shows 68,000,000 stars.

Mechanical Progress.

The New Gunboats.

The Board of Naval Bureau Chiefs is considering the designs of the six composite gunboats authorized to be constructed by the last Congress. It was the intention to make these new vessels midway in size between the "Petrel" type and the "Machias" class, so they were fixed at 973.6 tons displacement, one purpose in keeping them just below 1000 tons being to permit of the assignment to their command of energetic junior officers who might aspire to command larger gunboats and cruisers. Since the size has been agreed upon, however, there have been shown evidences of a disposition to reopen the subject and build two large and two small boats, the latter especially designed for use in the upper Chinese rivers, but it is improbable that this scheme will prevail, as the necessity for American gunboats in such waters is not apparent in time of peace, and they could not pass forts in time of war.

The boats have been given a spread of canvas of 11,000 square feet. It would be desirable to give them more, but this could not be done without infringing upon the space otherwise needed. This amount of canvas practically makes the gunboats full-powered sailing crafts, and in this they will be much different from any other of the vessels of the new navy.

The Construction Bureau has adopted this view in consideration of the peculiar service for which these vessels are destined on foreign stations, where they may be safely placed instead of larger ships, in the interest of economy, and will thus often be in places where coal is difficult to obtain. For service in Samoa, in the Gulf of Mexico, and in the Caribbean sea, and on the expensive Bering sea patrol, where speed is not an object at all times, the Chief Constructor holds that sail power will make the vessels of great value, and that they will be the most economical cruisers of the navy.

The Warship Chicago.

When the United States steamship Chicago goes out of commission at the New York navy yard she will have been practically retired from the navy service for at least two and perhaps for three years. It is the intention of the Secretary of the Navy to modernize the ship in every respect, and while the necessary changes would occupy many months under ordinary conditions, the particular work will be long drawn out because of lack of ample funds to carry out the project. At the last session of Congress an appropriation of $200,000 was secured to continue the work on the new engines of the vessel, which will be built at the New York navy yard.

Some of this work has already been executed, but the appropriation is entirely insufficient to complete the new machinery, which will cost about $500,000. It is the design to put in new boilers, including some of the new tubulous type, and new engines, and if all necessary funds were available this work would consume at least eighteen months. In addition to this, extensive changes are to be made in the battery of the ship, and the six-inch guns are to be replaced by five-inch rapid-fire guns. The Ordnance Bureau has no money at present to do this, being under the necessity of practically closing up the gun shops at the Washington navy yard, owing to the failure of Congress to provide the necessary appropriations. Then the contractors have a great deal of work to do on the Chicago, including a complete change of the rig of the ship, and they also have no money for this purpose. So all three of the bureaus must look to Congress at the next session to supply the means to prosecute their work, and as the funds will not be available before July, 1896, and the work once begun will require a year or two for its completion, the prospects are that the Chicago will have a long rest after the hard services she has had during the past ten years.

The naval engineers are about to begin an interesting set of experiments on boilers, which will probably determine the type of boilers to be placed on the Chicago. The large lake steamer Northwest, built at Cleveland, has been placed at the disposal of the Navy Department by the owners, for an exhaustive test.

As illustrating the loss of fuel which may arise from improperly banking fires under steam boilers at night, the *Electrician* cites an instance in which it was the practice to bank the fires at 6 P. M., and close the main damper of the flue, leaving the fire-doors open. The boilers were of the water-tube type, and at the time of banking carried 100 pounds steam pressure. The main damper was not perfectly tight, and sufficient air was drawn in to cool the boilers until the pressure had fallen to ten pounds, when the fires were opened at six o'clock the next morning. Subsequently the practice was changed by closing the fire and ash doors, and by also closing hand-dampers in the flues, which were found to be tighter than the main dampers. As a result, the steam pressure in the morning was invariably found to be at least forty pounds, and the bank of coals, which under the previous condition was more or less consumed, was apparently in the same condition as when the fire was first banked.

While it is true that good bargains may be sometimes made in the purchase of second-hand machinery, these cases are exceptions and not the rule. Most of the second-hand machines offered for sale are for the purpose of supplying their places with new and improved ones; and although such machines may to all external appearance be in good working order, the purchasers generally find out when it is too late to repent that they have made a mistake in their purchase, and the machine, although it may turn out good work, is not capable of turning out a sufficient quantity in a given time to enable him to successfully compete with his neighbors in the same business. The rapid improvements that have been made in all kinds of mechanical devices within a few years render it reasonable to expect that machinery, whether for working wood or iron, built ten or fifteen years ago, cannot possibly have the same improvements as those of recent manufacture.

A great deal has been published in engineering journals about scale in boilers, and yet very little has been said about the accumulation of it in feed and blow-off pipes. There are men who maintain that scale cannot accumulate in pipes in which the water is circulating constantly, or nearly so, as in the case of feed pipes and external and internal circulating pipes, but cases cited will show how fallacious such opinions are. As a matter of fact, these pipes often fill up in a remarkable way, the deposit choking them to such an extent that it becomes a source of positive danger.

The best preventive of warping bars is a cool ash pit. The best bar made can be speedily destroyed by allowing a pile of non-conducting ashes to accumulate in the ash pit, and then throwing down a layer of incandescent fuel on them to radiate its heat upward on the bars, and to heat the incoming air so that it cannot keep the bars cool. A clean pit with a couple of inches of water on the bottom will do wonders in the way of keeping the grates in good condition.

If a belt will not run a machine unless it is as tight as the strings of a bass viol, then it is time the pulleys were changed for broader faced ones, and a wider belt put in place of the narrow one. A belt of the proper width to perform its work with ease can be run on by hand as easily as it can do the work required of it.

Electrical Progress.

Insulating With Asbestos.

Enormous quantities of fine copper wire are used in constructing dynamos and motors. It is necessary, however, before this wire is wound into coils, that it shall be coated with some insulating material so as to compel the electric current to go from end to end, instead of escaping laterally. In practice this insulating material is a knitted web of cottou. But when at work, especially if overtaxed for a few minutes, a dynamo or motor will often develop considerable heat in the coils. Their effect cauuot hurt the copper, hut it may easily ruiu the cotton. By destroying the iusulation in this manner one can ruin the whole machine in a very short space of time, involving not only a loss in the investment, but also paralyzing important industrial operations for hours or days until the damaged device can be replaced with a new one. Builders of electrical generators and motors aim to avert overheating by adapting the proportions and mutual relations of the several parts of these machines to the work they are expected to do, and with the aid of automatic regulators and other means the intelligent user tries to avoid subjecting them to undue loads. But while the evil complained of is of less frequent occurrence now than formerly, perhaps it has not been effectually overcome.

It has been proposed to deal with this trouble by covering the wire with an incombustible material, which shall at the same time be a non-conductor of electricity. Asbestos, a fibrous mineral substance, meets these requirements admirably. Cloth for theater curtains and mittens for workers in iron and glass have been made from it, but it is a difficult and costly matter to draw it out into a fine and even thread suitable for weaviug it into a thin fabric. A coarse one is undesirable, since it would add greatly to the bulk of the coil, to say nothing of the cost of the extra raw material. But it is announced that a Providence, R. I., man has succeeded in adapting asbestos to this use, and has taken out patents on his methods. The Providence *Journal* declares that the thickness of the thread which he obtains from this material "compares very favorably with double-wound cotton." A current that would render a copper wire redhot, and would burn out the ordinary insulating covering instantly, may he used under asbestos without injury. Besides being incombustible, this substance also offers high resistance to the passage of electricity, and thus exhibits the essential quality of a good insulator. It looks, therefore, as if that inveutiou might prove of much valuc, if it does not add seriously to the cost of electrical machines.

Cost of Municipal Electric Lighting.

Prof. W. J. Meyers makes a neat little demonstration in the *Political Science Quarterly* of the fallacies of municipial book-keeping as applied to electric lighting. The report of the superiutendent of the Chicago electric light plant reports the annual cost as $96 per lamp, against $102 per lamp paid by private companies. But an analysis of the figures shows that the superintendent made no allowance for water consumed, nor for interest, nor taxes, uor insuraucе nor depreciatiou of plant. Adding in a proper estimate for these items, the truc cost is shown to be $167 per lamp. This is in line with the results obtained by Mr. Francisco in his instructive examination of the alleged economies of municipal ownership. The economies are almost iuvariahly ou paper merely, and a little figuring will show it.

A BRIDGE which is being built to span the Chuyahoga river at Columbus street, at Cleveland, Ohio, will be uulike anything of the kind ever constructed in this country. The hridge is to be worked by electricity and compressed air. It will have a double swing, the halves meeting at a common center aud locking. The span will be 115 feet long. The material will he steel throughout, and the electric current which will operate the dynamos will he obtained from street railroad wires. The new bridge will swiug in twenty-five seconds. The safety gate, signals, drops, and all auxiliary machinery will be worked by compressed air from the bridge-house, while the bridge proper will be propelled by electricity.

IRRIGATING by electricity is to he given practical test in the San Bernardino valley. The San Bernardino Electric Light Company has arranged an eight-mile circuit to cover the farms and orchards of the vicinity, aud by meaus of stationary pumps and movable motors the water for irrigating purposes will be distributed. The plan is for the formatiou of small districts along the line of circuit, each district to have the use of a motor. It will be attached to a pump a certaiu number of hours, just as irrigating ditches are open for regular periods, theu moviug into the next field counected with the wire, the current turned on, aud each field iu the district served in turn and as the water is needed. The cost of pumping by the electric motors is estimated at $1.15 per month per acre, or less than $7 per acre for the irrigating season at its longest. Water rights cost from $100 to $150 per acre, so that the cost of irrigating hy the proposed method is less thau the interest on the cost of a water right if purchased outright.

A NEW TYPE electric locomotive has been made iu Philadelphia for handling heavy freight and switching. It resemhles the ordinary consolidation type. There are four pair of drivers coupled together by connecting rods. The drivers are fifty-six inches in diameter, the end ones only being flanged. The motors, four in uumber and alternating in position, are of the Continental ironclad type, the field magnetics consisting of two steel castings haviug two field coils placed at the ends of the motors. The motors are wound for 800 volts at 225 revolutions, which equals thirty-five miles an hour. When in multiple each motor will give about 250-horse power, and there will be a constant drawbar pull of over 10,000 pounds. The controlling apparatus in the cab is so arranged that the engineer sits at the right side looking forward, no matter which way he is normally running. The total weight of the engine is about 134,000 pounds.

ARTICLES of iucorporation have been filed with the Idaho Secretary of State of the Salmon City, Lemhi county, Electric Light, Power and Water Company, with a capital of $150,000. The directors are Edward Mingle, W. F. Boxwell Jr., H. E. Ostranden and A. D. Walker of Salmon City, and B. C. W. Evans of Butte. This compauy is to supply electricity, water works and a telephone system to Salmon City and Yellow Jacket, Idaho, and Red Rock, Montana.

Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O., Jan. 25, 1894.

The American Mining & Milling Machinery Co., Cleveland, O.:

GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 700 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4⅞ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows LESS; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with LESS than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,

CLEVELAND IRON ORE PAINT CO.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER DISTRICT.—The Treadwells are prospecting with a six-stamp mill on a ledge of rock upon which they are tunneling, six miles above Sutter on Sutter creek. Wm. Castle has charge of the work for the owners.

Butte.

GENERAL ACTIVITY.—*Register:* Mining in Butte county is returning golden profits to nearly all lucky enough to own a mine in the county. Out at Bangor the Catskill is working the richest gravel ever worked in the blue lead. The famous Banner quartz mine is said to have returned its owners $100,000 above expenses in less than 100 days. The Denver mine has struck a rich body of quartz. The Gold Bank is just what its name implies. The big tunnel is being pushed ahead with great activity, and by fall will be near the rich lode, which can then be worked very cheaply. The Magalia mine will be opened this spring, and this is known to be one of the richest placer mines in all California. The Aurora, Oro Fino and other mines in the Magalia section, will all be taking out gold this spring. At Enterprise all the mines, both quartz and gravel, are paying well. At Oregon City three great quartz mines are being worked. On Wyman's Ravine fifteen men are taking out gold. At French Creek the miners are getting excellent returns. At Cherokee the mines are paying good wages to nearly 200 men.

Calaveras.

THE ESPERANZA MINE.—At the Esperanza the management is pushing the work and by the middle of next month the 20-stamp mill will be crushing quartz. In the new company, Samuel P. Ely, of Cleveland, Ohio, is chief owner.

Inyo.

NEAR MODOCK.—The south tunnel of the '95 mine shows sixteen inches of ore in the face, 130 feet from the surface, assaying $80 in gold 94 ozs. silver per ton. The north tunnel of the Gold Ridge mine has six inches of ore averaging $94 in gold and 153 ozs. silver per ton. Two hundred and nineteen sacks of ore from the last named mine were shipped April 20.

The Inyo *Index* reports that the Caster brothers lately found a $65 nugget in Mazourka canyon.

ARRANGEMENTS CONCLUDED.—Geo. T. Rives has concluded arrangements with the Inyo Canal Company to furnish water for a mine in Inyo that he has sold to St. Louis parties. He will be superintendent of the mine, and will commence the erection of a mill immediately.

Mono.

BODIE CONSOLIDATED.—The yield of the Bodie Consolidated mine for the week ending April 28th was sixteen tons of ore from the workings between the 300 and 400 levels. The estimated value of the ore is about $45 per ton. Will commence crushing ore at the Bodie mill about May 2d. The south drift from the east upraise, 42 feet below the 300-foot level, has been extended nine feet. The ore in the face is from eight to ten inches wide and of good grade. Have started stoping out ore north and south from the above drift. The ore stope from the winze below the south drift from No. 1 upraise, 300 level, is about the same as last reported.

Nevada.

TO BE SOLD.—The Rainbow mine, in God's Country, is to be sold at sheriff's sale to-day, to satisfy a judgment in favor of the men who filed liens on the mine.

THE ENGLISH MOUNTAIN. — Chris. Mallen has gone up to the English Mountain mine to inspect the property. He has been offered the superintendency.

TOO MUCH WATER.—*Union:* The Culverson mine, at Graniteville, has been closed down, the flow of water being so great that the pumps have been unable to handle it. It is expected that new and larger pumps will be procured and until then operations will remain suspended.

WILLOW VALLEY DISTRICT. — The Montana mine was bonded some time ago to Mrs. R. E. Lane, who has eight men at work developing the mine; the prospects are encouraging. The shaft has reached a depth of 400 feet. A steam-power hoisting and pumping plant is on the mine and has a capacity sufficient to admit of sinking 1000 feet.

The Old Home mine, at Blue Tent, has been bonded to F. C. Beckwith, of London, and will be worked.

The Mountain View Mining Company, of Washington, will put up a mill at their mine on Canyon creek.

The Mayflower mine will also put in additional milling facilities.

Plumas.

BUSY AT WORK.—The Quincy Mining and Water Company is reported running three monitors.

Shasta.

A CORRECTION.—Writing from Redding under date of the 1st inst., Mr. W. D. Swezey, president of the Eureka Tellurium G. M. Co., referring to a recent statement regarding rate of wages paid by the company, says: "We pay from $4 per day down to $2.50, which is the lowest price that we pay to any miner."

Sierra.

WILL RESUME.—At a meeting of the owners of the Gold Bluff mine, near Downieville, this week, it was decided to settle the company's indebtedness and resume work. The property was recently attached by John Costa of Downieville and others for $20,000.

THE ALASKA. — The strike in the Alaska mine has proven to be a good one. The Alaska Company has bought the Grizzly ledge, situated near the Alaska, and it is also producing good ore.

SHOWING UP WELL.—The North Fork drift mine is reported "looming up big." The gravel averages $3 per carload—a paying proposition.

Siskiyou.

ON THE KLAMATH.—Messrs. Souger and Dame of Ashland, Or., who have leased the McConnell and Quinn and Pacific mines on the Klamath river at the mouth of Humbug creek, have gotten them almost ready to commence operations. The former mine has in fourteen seasons produced $300,000 and but four of the forty acres have been worked.

MINING NOTES.—*Journal:* At the Empire quartz mine on Empire creek, Klamath river, a twelve-foot ledge has been found, without reaching the back wall, and comprises rich sulphurets paying from $3 to $500 a ton, which are sent to the Selby Smelting Works, on account of not being able to save the gold in the mill at the mine. Mr. Iuuker intends putting in a concentrator to work some of the ore and will send the balance below, or such as will realize a profit, as the cost of shipment amounts to $30 a ton.

The Black Jack and Klamath Consolidated companies, in the Cottonwood mining district, are each working two shifts. The latter company has started its second and third tunnels.

The Espey Mining Company have their surveyor at work running the line for their ditch which, when completed, will carry 1000 inches of water onto the Horse creek mines. C. O. Barlow, who has charge of the work on the Shasta river below Hawkinsville, has completed the foundation and is now at work on the structure for the two water wheels and the thirty-ton pump. James Quinne, who had charge of the work of extending and widening the ditch which is to be used jointly by the Espey Mining Company and the Yreka Electric Light Company, has finished his work and has ready for use a canal carrying 6000 inches.

The Portlaud company which bonded for a short term the W. H. Smith and Brass Wire gulch claims, near Henley, are now working the former claim, which has been opened up to great advantage.

The Omaha and Salt Lake capitalists who bought the big low-grade porphyry dike in the Cottonwood mining district, near the Klamath river, have had another ten-ton sample crushing made at the Jillson mill, with good results.

Austin & Co., of the Greenhorn blue gravel mine, about a mile below Yreka, realized over $1000 for last week's work, the gold being in large grains, with several nuggets of the size of beans.

Tuolumne.

GRAVEL DEPOSIT TO BE WORKED.—A company composed of Sacramento and Tuolumne men was incorporated this week with a capital stock of $300,000 to work 200 acres of rich gravel deposit eleven miles east of Sonora, on the Tuolumne river. Operations will commence at once.

NEVADA.

Storey.

The following are the latest official reports:

CHALLENGE—From top of the joint Confidence and Challenge raise from the surface tunnel a west crosscut was started during the week, which is now out 10 feet; the face shows quartz having no value.

CROWN POINT—The raise from the east crosscut from the south lateral drift on the 700-foot level is now up 49 feet, having been extended 9 feet since last report. The formation on top is the same as last reported. Stopped the south drift on the 700-foot level and started a crosscut from it to the west, 37 feet south of No. 2 east crosscut. It is out 8 feet, and the face is in a mixture of porphyry and clay. No work has been done in the mine since the evening of the 25th ult. From the ore extracted during the week, and from that accumulated in the dumps at the mine, have shipped 657 tons to the Mexican mill for reduction. The average battery for the week was $9.61, of which $8.59 was gold.

BELCHER—On the 300-foot level the joint Belcher and Seg. Belcher south drift is in 180 feet from the shaft; the face shows porphyry. They have hoisted during the week and stored in the ore-house at the mine 43 tons of ore, the average top car sample of which shows an assay value of $17.54 per ton.

SEG. BELCHER—On the 200-foot level the southwest crosscut from south lateral drift is out 22 feet; the face is in porphyry and quartz of no value. Have hoisted during the week and stored in the ore-house at the mine 11 tons of ore, the average top car sample of which shows an assay value of $25.95 per ton.

JUSTICE—The winze from the drain tunnel level between No. 1 and No. 2 chutes was sunk 20 feet, making its total depth 32 feet. This winze is following a streak of low-grade ore assaying from $7 to $10 per ton.

SAVAGE.—In the Savage on the 950-ft. level the north lateral drift started from the west side of the station is advanced thirty-five feet on the vein. The north drift from the east crosscut fourth floor, continues in quartz and porphyry. The south drift from the face of the sill floor southeast drift is advanced 110 feet; face is in quartz giving low assays. On the 1,100-ft. level in the south drift they have started an east crosscut and advanced the same ten feet; face is in quartz and porphyry. They continue to extract some ore on the eighth floor of the old stopes. On the 1,050-ft. level the east crosscut from the fourth floor 300 feet south of the shaft is advanced forty feet. This drift reached the east clay of the vein and was stopped. The west crosscut from the tenth floor of the south ore stoper is advanced twenty feet; face in quartz and porphyry.

CON. VA. BULLION.—The bullion statement of the Con. Virginia mine for the quarter ending March 31st shows total ores worked during the quarter, 3527 tons and 870 pounds; gross yield of said ores, $100,427 36, cost of extraction, $55,912 07; cost of reduction and transportation, $24,692 04; net proceeds, $19,823 25. The bullion tax on the net proceeds amounts to $991 50.

THE DAYTON DREDGING PLANT.—The Carson River Placer Mining and Dredge Company started up its entire plant last week, and is in operation. The concentrating plant on the shore is doing good work and quicksilver and amalgam are being caught in some quantities by the devices in the screening plant. The company will make a lengthy run. About twenty men are employed. Capt. Davis says the working of the plant thus far shows that each concentrator will handle from fifteen to twenty-four tons of this pulp each twenty-four hours, and the pulp or screened sand yields from three to forty per cent. sulphurets. These sulphurets assay from $12 to $150 per ton. All of the factors are continually changing each minute of time that the machinery is running. For the short time in which the plant has been running since its completion, the output was 40½ tons per twenty-four hours, averaging in assay value of sulphurets alone $1,126. The factors for free material, quicksilver and amalgam, vary greatly. They vary from a few cents to several dollars per ton of the material hoisted from the river. The actual practical results can only be determined by longer practical work with complete plant. Thus far the only actual known returns of quicksilver, free material and amalgam have been at the rate of twenty cents per ton for each ton of material hoisted from the river. In many places in the river the returns will go far above this figure, and at other places the returns for quicksilver, amalgam, etc., may go far below and amount to practically nothing.

STARTED UP AGAIN.—The Pittsburg gold mines, eighteen miles southeast of Battle Mountain, which have been idle for two years, started up again on the 1st.

Add Nev

FIVE HUNDRED FEET DEEPER.—The new tunnel in the Wilson mine, near Yerington, will tap the mine 500 feet deeper than the present workings. This will give a new lease of life to the camp.

NYE COUNTY.—Belmont *Courier:* Henry Metz writes from Moutgomery to W. Brougher that the gold mines are looking well in Southern Nye county, and that the company will put up another Huntington mill soon. Within the past month thirty new tents have been pitched in that district by prospectors and miners.

ARIZONA.

"OLD GLORY."—*Star:* J. G. Hilziuger, who has just returned form the "Old Glory" reports quite a boom in mining in that region. Some fine discoveries have been made in a canyon near that mine, and the whole neighborhood is being covered with locations. "Old Glory" is practically shut down, but the company is soon to be reorganized, with an additional $40,000 or so of capital, and then work there will be pushed.

EMBALMED AND SENT HOME.—*Journal-Miner:* J. B. Tomlinson of the Mescal Mining company had the bodies of the miners who were killed by the explosion in the Ohio mine embalmed and shipped to their homes in Colorado at the expense of the company.

AT HARQUA HALA.—*Sentinel:* Ramon Ochoa returned from Harqua Hala Tuesday morning. He said that the Harqua Hala Bonanza mill shut down last Saturday, and the mine of the same name is a thing of the past. Only one pillar of ore remains. Sixty men were discharged on that date and are now scattered in all directions. The tailings will be worked by the cyanide process and will employ a few men for about eighteen months. The mine has been in active operation for the past six years and has produced several millions of gold dollars during that time. The shutting down of the mill was not unexpected for it had been rumored for several months that the ore was nearly exhausted.

THE OLD CROOK MINE.—*Courier:* O. W. Stall and Fred Sattes are working the Alligator mine and mill with marked success. Stull a few days ago brought forty-four ounces of gold from those properties, which was shipped to the San Francisco branch mint. The Alligator is the old Crook mine.

AT EHRENBURG.—The Los Angeles *Times* says: "Lum Gray's outfit, with mining tools and men has started for Mr. Gray's new property at Ehrenburg. The intention is to first develop the property before putting up a mill. Sinking to a depth of a hundred feet will be done on the ledge in two places. Then a tunnel will be put in connecting the bottom of the shafts. This will open up the ore body and show at least one big block of ore to work on—if the ore is there. All proving satisfactory, a mill will then be built, a narrow-gauge road put in to the Colorado, and steamer connection made with the Southern Pacific. Colorado people are interested in the project."

CHANGE OF FUEL.—On the 1st the Arizona Copper Company began using coal as an experiment, instead of wood. This throws out of employment 200 or 300 hurros and their drivers.

A NEW CONCERN.—Articles of incorporation of The Tucson Mining and Smelting Company, with headquarters at London, England, and a capital stock of £20,000 (about $100,000), divided into 20,000 shares, were filed with the Pima county recorder this week.

COLORADO.

BOULDER COUNTY PROSPECTS.—The new mill on the Pine Shade is in operation and is proving a great success in handling the ores from the big ore body. The shaft is now 210 feet deep and the vein has been explored more than fifty feet between walls. Three drifts are run in each level seventy feet long through this mass of mineralized matter, one on the foot and one on the hanging-wall, while the third is in the center of the ore body. The walls are perfect with a streak of talc on them, making it one of the best-defined lodes in the county. Tracks are laid in each opening, and iron cars convey the ore to the shaft, where it is dumped into a skip of 2500 pounds capacity and hoisted to the surface. Every pound of the material broken in the mine is dumped into the mill and averages $10 per ton.

The mill building covers 263 feet in length by sixty feet wide, and is so admirably constructed that everything works automatically from the time the stuff reaches the scales until it comes out pure gold. The mill is built in twelve terraces, as follows: Scales room, machine room, crusher and carpenter shop; 2, ore bin; 3, feeder floor; 4, twenty-stamp batteries; 5, amalgamated copper plates; 6, Gilpin county bump tables; 7, Johnson concentrators; 8, drying room; 9, leaching room, in which are placed four large iron tanks into which the concentrates are put; 10, precipitating tanks (2); 11, refining and assay room; 12, sump tank, into which all the leaching liquids run and are caught, then repumped back to the drying room and used over again. From the time the ore is taken out of the mine until the gold is run into a $2000 brick it is only handled when the cleanup is made. The mill has a capacity of 100 tons daily. There are four batteries of five stamps each, with a drop of eight inches at a speed of 100 drops per minute. The mill is the most perfectly constructed in Boulder county, and is lit up by thirty-six electric lights, which makes the building as light as day. The shaft has also electric lights in it, and is most complete in its equipments. The motive power is furnished by an eugiue of 100-horse power capacity, and a huge tubular boiler. Water is furnished for the mill and machinery from the St. Vrain by two pumps through a pipe line 3400 feet in length, and discharged into a huge tank of 20,000 gallons capacity. A more complete mill from beginning to end cannot be found in Colorado, for it saves a very large percentage of the precious metals contained in the ores. There will be no raw material such as smelting ore and concentrates shipped to the smelters, as the extraction of gold and silver will be done on the property.

A BIG DEAL.—Cripple Creek *Miner:* The Victor, Isabella, Zenobia, Pharmacist, Orphan Belles group and other minor claims and groups of claims, all located on the north slope of Bull hill, have already or soon will be transferred to a French syndicate. The Isabella company own about 160 acres of patented ground, the Orphan Belles thirty-four acres, Pharmacist twenty-one. The Victor is a full claim and the Zenobia contains about eight acres. In all fully 250 acres will be controlled by the syndicate, for which they will pay in the neighborhood of $1,700,000.

SYSTEMATIC MINING.—A remarkable combination of systematic mining operations was recently organized in New York by Clarence B. Richardson. It is proposed to locate 100 gold-mining claims in Colorado. Out of these will be selected ten which have the best surface indications, and upon each of the ten will be sunk a shaft 100 feet deep. Mr. Richardson, who will have the management of the enterprise, is assured of the ablest expert assistance that can be obtained in the country. It is certainly a novel enterprise and does credit to the ability and originality of Mr. Richardson.

INCREASED WAGES.—Notice is posted in Aspen that on and after May 1st the wages of miners who are working for $2.25 will be increased to $2.50 per day.

BRITISH COLUMBIA.

GENERAL NOTES.—The War Eagle shows a breast of eleven feet of ore.

Every discovery in Trail creek is now said to be exactly like the War-Eagle or Le Roi ore.

On April 10th the Le Roi shipped fifteen tons and the War Eagle twenty tons, aggregating $1,750 in value.

The Rio, near the Surprise, Slocan, has been bonded to San Francisco parties. It is high grade dry ore.

The machinery on the Le Roi, Trail creek, will be increased to the capacity of raising 100 tons a day.

A ten-stamp mill is to be started on the Poorman mine near Nelson as soon as the roads are repaired.

The Three Forks concentrator has been shut down temporarily for repairs to the flume. About 400 tons are on hand for treatment.

Good ore is said to be found at the head of Champion creek, which enters the Columbia river sixty miles below the junction of the Kootenay.

The Hall Mines, limited, has called for tenders for constructing an aerial tramway to Nelson, 4½ miles, capable of conveying 100 in ten hours.

A party of gold miners are said to be leaving Buffalo shortly for the Fraser river. Each will contribute $750 to be spent on machinery.

The Consolation mine, Big Bend, is cleaning up about $450 a week. A $50 nugget was taken out a short time ago and in four weeks the total product was $2,500.

The new concentrator is at work on the O. K., Trail creek. The ore is first milled and the free gold taken out, then the tailings concentrated, saving ninety per cent. of the metal.

OREGON.

JACKSON AND JOSEPHINE COUNTIES.

GENERAL NOTES.—W. H. Hamlin has sold his placer mines, near Grant's Pass, for $3000, to Portland men, who are engaged in fitting them up for work.

Some of the placer miners—those mining in dry gulches, etc.—have been compelled to

clean up, on account of the scarcity of water.

Brown & Band have finished cleuning up at the Miller mine, in Farmers' Flat district. They got $2500—a good result considering the short water supply.

Logan, Phillips & Kerschner, who are prospectiug a ledge near Kerbyville, have tested several tons of the ore with un arrustru, and will probubly put in a five-stamp mill.

H. Gendar has some rich rock from the Linchpin ledge on Wagner creek, some of it going us high as $200 per ton. He has an arrastra at work, crushiug ubout two tons per day.

J. W. Virtue, after whom the Virtuo mine in Baker county was named, is prospecting ou the Hanley ranch, in the Applegate country, in the interest of C. J. Eddy of Portland.

The copper mines on Illinois river, Josephine county, which huve lain idle so long, are ugain attracting the attontion of capitalists. A working test of the ore will soon he made, and if it proves satisfactory extensive operations will he commenced.

The Mountuin Lion mine, Missouri Flat district, which reverted to Bailey & Co. somo timo ago, is running on full time.

DOUGLAS COUNTY.

Evans & Clark, who are engaged in prospecting the Elizuheth quartz claims on Mule creek, are talking of putting up a ten-stamp mill. Burt & Tiller have struck it rich on Rogue river, below the "devil's stnirs," und intend to rig upn puup aad work their ground on a larger scale than ever. Mnrks & Co. are running two giants day and night at their mines on Mule creek. They have had considerable trouble with their ditch, hut still stripped an acre and a half of hedrock. Their foreman says thoy are good for an acre and a half more hefore the water quits.

WASHINGTON.

METHOW DISTRICT.—The nuaber of men employed in the various mines in Methow District ure as follows: Saturday employs four men and running two shifts; Friday, two men; Blue Grouse, two; Bismark, two; Lookout, six men und three shifts; California, five; Derby, four and two shifts; London, two; Ransomette, two, Highlnnd Light, four and two shifts; Mountain Lily, two; Hidden Treasure, three; Rising Sun, two; Philadelphia, two; White Swan, two; Small Change, two; Grey Eagle, twelve; Four Aces, six; Tiger, two; Paymaster, two; Gruhstake, two; Diamond Flush, two; Mills, two; Eva, four; Captaiu Hanson, two; Mr. Griggs, five. Besides these there must he twenty-five more at work and at every point of development work the prospects are excellent.

PESHASTIN DISTRICT.—The Blewett Gold Mining Co. are fitting up their twenty-stamp mill with a view of starting up the mill about the first of May. They have now about 1,000 tons of ore in their bins.

Baldwin and Kirk were very successful in their first arrastra clean up, the ore netting them over $20 per ton.

King & Co., who are working about two miles above Blewett on the Peshastin, are reported to have struck a rich body of gold ore.

WYOMING.

BIG LARAMIE PLACERS. — The Cheyenne *Tribune* publishes the following in relation to the Big Laramie placers: A private letter was received in this city hy a heavy mining promoter from a prospector at Dodge City on the Laramie river, in Albany county. The letter states that after a close assay of the placer mines helonging to the Cheyenne & Iron Mountain Company, on that stream, the ground has been fouud to run from 75 cents to $1.50 per yard. Each pau has shown from 200 to 225 colors of gold.

MEXICO.

CHIHUAHUA.

THE CORRALITOS MINE.—At the Corralitos mine in the State of Chihuahua, Mexico, about 500 men are at work. The payroll averages over $36,000 monthly.

Patentable and Unpatentable Inventions.

In an opinion read by Judge Brown in the Supreme Court of the United States, on the 22d ult., the distinction betweeu patentable and unpatentable inventions was declared. The case in hand came from the Circuit Court for the Northern District of this State, i uvolving three patents for the manufacture of belt pulleys and for the product of that process, which Philip Medart et al. alleged had been infringed by the Risdon Iron and Locomotive Works. The court below gave judgment in favor of the claimants. The Supreme Court reversed this decision. Discussing the claims of the patent for the manufacture of the pulleys, Justice Brown said: That certain processes of manufacture are patentable is as clear as that certain others are not, but nowhere is the distinction between them accurately defined. There is somewhat of the same obscurity in the line of demarcation as in that between mechanical skill and inveution, or in that between a new article of manufacture which is universally held to be patentable, and the function of a machine which it is equally clear is not.

It may be said, in general, that processes of manufacture which involve chemical or other similar elemental action are patentable, though mechanism may be necessary in the application or carrying out of such processes, while those which consist solely in the operation of a machine are not. Most processes which have been held to be patentable require the aid of mechanism in their practical application; but where such mechanism is subsidiary to the chemical action, the fact that the patentee may be entitled to a patent upon his mechanism does not impair his right to a patent for the process, since he would lose the benefit of his real discovery, which might be applied in a dozen different ways, if he were not entitled to such patent. But, if the operation of his device be purely mechaaical, no such considerations apply, since the function of the machine is entirely independent of any chemical or other similar action. * * * * It is equally clear, however, that a valid patent cannot be obtained for a process which involves nothing more than the operation of a piece of mechanism, or, in other words, for the function of a machine.

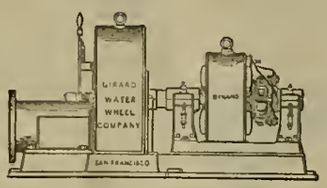
A Salt Laker's Description of California Mines.

Mr. E. S. DeGolyer, who has just returned from a visit to his properties in Calaveras county, California, gives a glowing account of the richness of the mines of that district. Mr. DeGolyer is the owner of the Gottschalk mine, which is situated ten miles north of the mines of the famous Utica Company, and south of the Keystone. When he visited Cripple Creek he thought he had seen the greatest gold possibilities the world ever had or ever would produce, but since he became interested in these California properties he considers that all former gold belts are outdone. This gold belt is on the original mother lode of the Sierras, lying low in the foothills and parallel to the range. The extent of the deposits and the richness of the ore have not yet been definitely ascertained, nor has even an approximation of the values been reached, but in places the vein of gold-bearing matter is known to be 120 feet thick, and in the case of the Utica, where the greenstone wall was cut through, another veiu seventy feet wide and of the same general character as the original was cut into. This Utica mine is now producing from $350,000 to $450,000 per month, and the Keystoue, at a depth of 2000 feet, is now paying monthly dividends of $120,000. This latter mine is in litigation on a question of end lines, aud four weeks ago extracted one ton of ore for the benefit of the experts in the case that rendered an assay value of $170,000 to the ton.

In connection with the title of the Gottschalk, Mr. DeGolyer's property, there is an excellent water right for power, and during the present summer Mr. DeGolyer will erect a stamp mill. He is not content with one mine, however, and has closed a deal for the purchase of the Donnellan. This is an "open air" mine, the vein lying up against the grass roots, and from the surface down everything has been milled for the past thirteen years. A hole is now down a few feet deep, but covering an area of one-fifth of an acre, and out of this hole, with almost no expense for mining, several fortunes have been taken out. It is the intention of Mr. DeGolyer to sink a shaft in the soft material of the ore vein, and go down for the contact of the original lode.

Speaking of this mother lode, the discovery of which was promised by geologists and practical miners thirty years ago, Mr. DeGolyer yesterday stated that the "wildest dreams of African riches would not begin to compare with the gold bodies on the western slope of the Sierras, where the origiual source of the gold of the Rocky mountains is located, and from which all the riches of the Pacific slope had their birth."—Salt Lake Tribune, April 25th.

American Girard Water Wheel.



Adaptable to all heads between 30 feet and 2000 feet, particularly where economy in the use of water and fine regulation are desired, as, for instance, the operation of electric dynamos.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXVII.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

Alameda.—In March, 1871, a letter from Livermore to the Alameda *Advocate* announced an oil excitement in Livermore valley. A well fifty-five feet deep commenced flowing gas which, igniting by accident, "burned brilliantly; there was a constant roaring going on at the bottom of the well, and the water was blue and smelled of coal oil and sulphur."

In 1890 there was a similar excitement at Pleasanton. "Gas and oil were discovered on the ranch of Joseph Brown, four miles east of the town. An inch pipe was inserted into a closed ten-inch well that had been sunk; the gas was ignited and it burned with a clear, bright flame." In April, 1891, there was another excitement at the same locality, which soon subsided.

During the excitement at Pleasantou several shallow wells were sunk at or near Martinez, and a small quantity of gas obtained at a depth of from fifty to eighty feet.

Amador.—"The gas well discovered in the buttes near Sutter creek many years ago, by prospectors in search of coal, is about to be improved and utilized. There is a flame now issuing from it that leaps six feet from the ground, and is eighteen inches across." [Newspaper excerpt.]

Butte.—A few years ago Mr. E. D. Sewell, of Butte creek, described a well which he sunk to a depth of seventy feet. The water was strongly charged with mineral matter. In sinking, he heard a continuous roaring sound which grew louder as the work progressed. The sound was attributed to rushing gas. This is a personal statement by Mr. Sewell.

Colusa.—This county is remarkable for being the theater of widespread solfatarie activity, of which Sulphur creek seems to be the center. There hot springs, quicksilver mines, sulphur fumaroles and petroleum springs are common. Hydrocarbon, hydrosulphuric and carbonic acid gases issue from the earth at many points. One flaming jet, before mentioned, resembles the fires of Barigazzo in Italy, and the Persian flames on the shores of the Caspian sea. It has not been extinguished since 1859, except at intervals.

This is probably the oldest example of escaping gas known in California. It lies 470 feet above the hotel at Wilber springs. I visited this very interesting locality in March, 1890, and found the gas burning with a lambent blue flame, tinged with pale yellow at the apex; the flame was very hot, and it issued from a small orifice and rose about two feet. The slime through which the burning gas escaped is black or very dark colored, but the inner surface of the opening is pale yellow, the effect of long-continued heat.

I have the statement of a gentleman who lived at Sulphur creek for some time, to the effect that he once extinguished the flame and found cinnabar crystals lining the opening from which the gas escapes. These he scraped away, and again lighted the gas; in two months a second examination showed that the crystals had been replaced.

It is said that if this fire is extinguished it will relight spontaneously; I do not credit this statement, but it might be inflamed by some accidental grass or forest fire.

Gas rises in bubbles not only in the bed of Sulphur creek and basins of the mineral springs, but in any shallow pool formed by rains or overflow of the streams. From this it may be inferred that invisible gases are escaping over the surface elsewhere. This will be readily conceded by those who have experienced the odors of hydrogen sulphide and sulphurous acid gases at this locality.

Contra Costa.—In 1888 a gas spring was discovered at Byron springs, fifty feet above tide water. A pipe was driven down thirty-six feet, through which some gas flowed. A second well was then sunk forty-eight feet and more gas obtained, but the find did not prove to be one of great importance. The second well is said to have passed through six feet of iron pyrites.

In 1888 a gas well was commenced one and a half miles from Lafayette and ten miles north of Oakland.

In 1890 I visited the ranch of Mr. J. G. Miner, who was investigating some superficial emanations of natural gas. At several points a pipe driven into the soft earth became an exit for a little gas which could be lighted if a burning match was quickly applied; and at others, by stirring the muddy waters in the creek bed, gas escaped which could be ignited.

At several places thick maltha issued from the ground, and a highly bituminous shale was seen cropping from the ground, which is well worthy of investigation.

Fresno.—The indications of natural gas in Fresno county are sufficiently encouraging to have induced capitalists to form prospecting companies, but I am not aware that any material success has attended such explorations.

(To be Continued.)

The Dead of the Sea.

An inquisitive Frenchman has thought it worth while to ask what becomes of the bodies, after death, of the numberless fish and other living creatures that fill the sea. Of course they all die, sooner or later, and yet it is an occurrence so rare as to be practically unknown for anybody who lives beside or on the ocean to come across the "remains" of even a single victim of the fate that awaits all things mortal. In the profounder depths putrefaction cannot take place, so if a dead fish once reached those calm, chill abysses he would be preserved until the end of time. Probably, however, no such peaceful repose awaits more than an infinitesimally small proportion of the finny folk, and no great accumulation of lifeless bodies exists at the bottom of the sea. The living eat the dead before they can make the long, slow journey downward. As a matter of fact, extremely few fish, and perhaps none, ever meet what is known as a "natural death." Almost always they are slain and devoured, and so put definitely out of the way.

Market Reports.

The Markets.

SAN FRANCISCO, May 2, 1895.

Silver was steady during the week, closing at about the same figures as the preceding week. The *Mexican Financier* says: Mexico does not want a too decided improvement in silver, as the country has begun to adjust itself to the new condition, and home manufactures and exports of products have been stimulated by the operation of the high rate of exchange. 'Tis different in the United States.

The metal market is unchanged.

The Leather Belting Manufacturers' Association advanced the prices of belting twenty per cent on the 22d ult.

San Francisco Mint Coinage.

The coinage of the San Francisco Mint for April was as follows:

Double Eagles	$1,610,000
Standard Dollars	100,000
Half Dollars	48,000
Dimes	70,000
Total	$1,828,000

The coinage for the first four months of this year was:

Double Eagles	$7,370,000
Eagles	242,500
Standard Dollars	300,000
Half Dollars	100,000
Quarter Dollars	320,000
Dimes	70,000
Total	$8,602,500

Mining Share Market.

SAN FRANCISCO, May 2, 1895.

Stocks sold up during the week, and, compared with April, this mouth opens with general activity. The foreshadowed Hale & Norcross decision and the improved appearance of the mine get the eredit for the advance in that stock to $1.55. That stock shared with Con. Cal. and Ophir the honor of being scarce and in demand.

John W. Mackay writes from New York that he will be here this month.

The following paid dividends in April:

Alaska-Treadwell M. Co., 37½c ₱ share	$75,000
Alaska-Mexican M. Co., 15c ₱ share	30,000
Homestake Mining Co., 25c ₱ share	31,250
Napa Con. Quicksilver M. Co., 20c ₱ share	20,000
Total	$156,250

The next assessment due is on Ophir next Tuesday, May 5th. The annual meetings of the Scorpion and East Sierra Nevada have been called for the 13th. The annual meeting of the North Star and Original Empire Mining Companies have been called for next Wednesday.

The following illustrates the changes of the week:

BOILERS may deteriorate from nonuse more than from continuous service with proper attendance. Such an instance is related by John A. Fish in *Power*. In his case, the boilers to be laid off were kept full of water to prevent internal corrosion, with the result that the large body of cold water caused condensation on the fire or air side of the tubes, and the resulting moisture mixing with the deposits upon the iron produced rapid corrosiou. This action has inclined engineers to completely empty their boilers, rather than to leave them full, taking off the plates so as to secure a free circulation of air and keep the sheets clean and dry. The boiler is thus always open for inspection, and any tendency to corrosion can be quickly detected.

The following are the nine longest words in the English langnage at the present writing:

Snbconstitutioualist.
Incomprehensibility.
Philoprogenitiveness.
Honorificibilitudinity.
Authropophagenarian.
Disproportionableness.
Velocipedestrianistical.
Transsubstantiationableness.
Proantitransubstantiationist.

Swiss firms have entered into a contract with the Japanese war office to supply a sufficient number of watches for one to be given to every soldier who has served in the campaign when the Mikado reviews his victorious troops at the close of the war. The watches, which will take the place of war medals, are to cost $1.50 apiece.

THE productiou of mica for '94 in the province of Quebec aggregated 400 tons. About 150 men were employed in mining it.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING APRIL 23, 1895.

538,219.—FRUIT PACKAGE—H. Baskervillo, St. Helena, Cal.

537,912.—LEATHER BLANKS—J. K. Bigelow, S. F.

537,913.—LOOP MACHINE—J. K. Bigelow, S. F.

538,150.—DAMPER REGULATOR—A. P. Buruham, S. F.

537,969.—BUTTON—Thos. Fahey, Spokane, Wasb.

538,076.—CAR COUPLING—C. W. Hintou, Los Angeles, Cal.

537,894.—WATER TANK—F. W. Krogh, S. F.

538,000.—BOILER—J. C. H. Stut, S. F.

538,050.—PUMP—W. Swabel, S. F.

538,056.—FOOD WARMER—D. R. Wilder, Los Angeles, Cal.

538,140.—REIN HOLDER—J. P. Wilson, Red Bluff, Cal.

538,006.—GAS BURNER—R. Wynell, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CENTRIFUGAL PUMP.—Wm. Swabel, San Francisco, Cal. Assignor of one-half to Isaac L. Burton of same place. No. 538,050. Dated April 23, 1895. This invention relates to centrifugal pumps. It consists of a case having an inlet opeuing at the center of one side, to which an iulet pipe is holted, a shaft passing through the opposite side of the case with a two-part runner or disk fixed thereon so as to rotate within the case. Each part of said runner has a spiral channel formed upon it so that the two form a tubular spiral, tapering from the inner end outwardly. Fixed radial partitions extend from the center of the runner to the augles where the spiral passages meet so as to complete the division between said passages. The case has a spiral discharge passage formed hetween its iuner wall and the periphery of the runner. The periphery of said runner operating close to the inner wall of the case at the point where the smallest end of the spiral discharge makes a junction with the largest end of the passage, so that the water received into the spiral channels of the runuer, discharges into the smallest end of the spiral discharge until the narrowest part reaches the point where the two merge into each other.

GAS REGULATING BURNER.—Robert Wynell, San Francisco, Cal. No. 538,006. Dated April 23, 1895. The object of this iuvention is to provide a deviee which is applicable to each individual gas hurner, and which serves to automatically regulate the supply of gas without reference to the variations in pressure which may take place, the deviee heing also applicable in any pipe or passage through which fluid or liquid flows under a variable pressure. It consists of a plug fitting closely in the passage in the interior of the pipe having spirally formed grooves or channels extending in opposite directions from one end of the plug to the other, said channels intersecting each other at two distinct points upon opposite sides of the plug wherehy the fluid is inspected and broken at each intersection and upon opposite sides.

BOILER.—John C. H. Stut, Oakland, Cal. Assignor to the Locomotive Feed Water Heater Co. of Bakersfield, Cal. No. 538,000. Dated April 23, 1895. This invention relates to that class of boilers in which a supplemental heater located within the fire-hox is connected at its lower portion by a pipe with the lower portion of the hoiler, and at its upper portion is connected with and is adapted to conduct the hot water or steam into the upper portion of the hoiler, whereby a complete circulation is maintained. The invention consists in an improvement in the form and construction of the supplemental heater (it heing jointless and tuheless, made of a single piece of metal and of circular cross section), whereby it can withstand the heat to better effect, is not likely to leak, and will not disturh joints hy its expaasion and contraction. It also consists in the novel construction, wherehy the circulation of the water may he observed, and also in a novel filtering and blowing off device in the pipe which connects the lower portion of the hoiler with the supplemental heater, the object heing to effect a perfect filtering of the water and deposit of the sediment and to control its blowing off readily.

THE sky is whiter over the cultivated than over the uncultivated portions of the earth's surface, because a great deal of coarse dust is present in the atmosphere in the former instance, with the result that a larger proportion of white light is diffused.

Assessment Notices.

OVERMAN SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Gold Hill, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of April, 1895, an assessment, No. 73, of ten cents (10c.) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, No. 414 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 11th day of June, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. D. EDWARDS, Secretary.

Office—No. 414 California street, San Francisco, California.

H. P. TAYLOR MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Liberty Mining District, Siskiyou county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth day of April, 1895, an assessment of Four (4c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 39 Merchants' Exchange, 431 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirty-first day of May, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on FRIDAY, the twenty-sixth day of July, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. HENRY SMITH, Secretary.

Office: 39 Merchants' Exchange, 431 California St., San Francisco.

ANNUAL MEETING.

The Regular Annual Meeting of the Stockholders of the Gold Ridge Consolidated Mining and Milling Company will be held at the office of the Company, No. 216 Post street, San Francisco, California, on Monday, the 20th day of May, 1895, at the hour at 3 P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and the transaction of such business as may come before the meeting.

Transfer books will close on Friday, May 17, at 1 o'clock P. M.

RICHARD PHELAN, President.
R. H. DALEY, Secretary.

Office, 216 Post St., San Francisco, Cal.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medica College, of New York City.

TAUGHT BY MAIL THOROUGH PRACTICAL

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

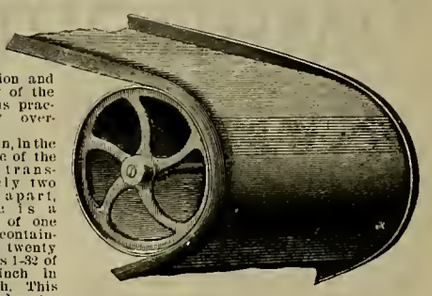
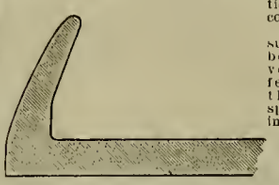
Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tulloch machines, and make all lengths and widths to order.





Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

H. G. BLASDEL, JR., Manager,

419 California Street, Haywards Building ..... San Francisco.

GATES ROCK AND ORE BREAKER

OVER 3000 IN USE THROUGHOUT THE WORLD

PRODUCES A MORE PERFECT CUBIFORM MATERIAL AND A GREATER QUANTITY IN A GIVEN TIME PER HORSE POWER USED THAN ANY OTHER CRUSHER ON EARTH.

PATENT SOLICITORS.

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

RISDON IRON WORKS.

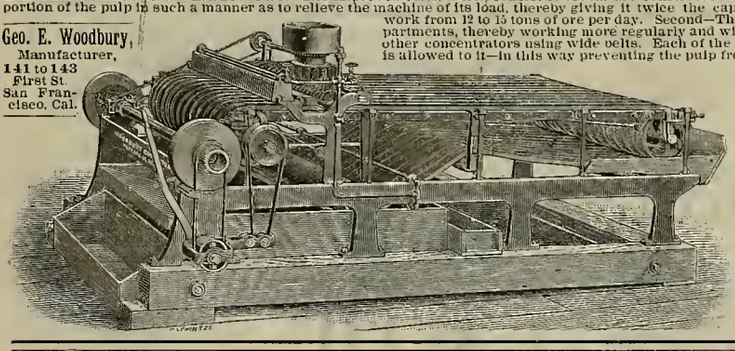
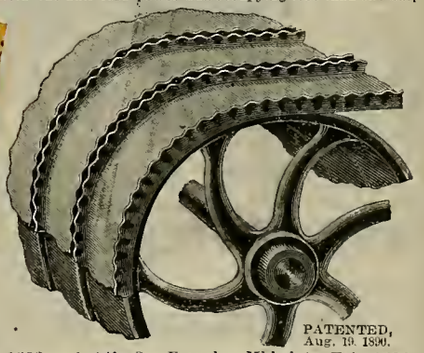
MAIN WORKS: Harbor View, San Francisco.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891, MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. **Price $575 f. o. b.** Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The Improved belts, which consist of seven, are constructed and arranged so as to allow each belt to rece portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enablin work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several partments, thereby working more regularly and with much less attention than is necessary other concentrators using wide belts. Each of the belts on this machine takes care of the pu is allowed to it—in this way preventing the pulp from running to the lower side of it, as is when a machine becomes out of level wide belts are used. Third—The belts perfect line, needing no adjustment to their running from side to side, as in ot centrators. Fourth—The belt surface proved by indentations and corr causing the Concentrator to save phurets and quicksilver, and perf work. Fifth—The belts have fluted rugated edges, to form an expanded which effectually prevents front ding. Sixth—The feed arrangement fect. Seventh—The machine is constructe iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury, Manufacturer, 141 to 143 First St. San Francisco, Cal.





PATENTED, Aug. 19, 1890.

This Concentrator took the 1st prize at the San Francisco Mechanics' Institute in 1890, 1891 and 1892, and at the California State Fair in 1892; it took the 1st prize at the World's Columbian Exposition, 1893, and at the San Francisco Midwinter Fair, 1894.

Travertine.

The mineral wealth of California comprises much besides its metals. Valuable alike for use or ornament are many other minerals. Among the rarest, yet most valuable, of these non-metallic substances is California travertine. It is a white, crystallized limestone, found in few parts of the State in quantity sufficiently large to be of commercial value. A deposit near Tolenas springs, Solano county, attracted some attention several years ago, but its irregularity of fracture made it impossible to satisfactorily dress or quarry it, and it was devoted to the humbler use of making a superior quality of lime, till fuel becoming scarce the work lapsed.

Recently a deposit has been discovered about a mile southeast of Bridgeport, Mono Co., which is the subject of the two accompanying illustrations. It is described in the last State Mineralogist's report as near the base of an extensive area of hilly country formed of hornblende andesite. Here four claims have been located in one block, but the most of the travertine is confined to two of them. The springs, which at one time were more numerous than at present, have built up a deposit of unknown depth, in what is apparently a basin-like depression; a large part of this mass consists of porous limestone, but in the center and eastern part deposits of a different kind have been formed. Here are eight distinct moles or ridges, seven of them nearly parallel and built up from ten to twenty-five feet above the general level. Running longitudinally through each of these, and generally nearly vertical, is a fissure, sometimes open and nearly two feet wide, and at others closed by a deposit of banded onyx (aragonite) or travertine. The outer portion of these ridges is formed generally of a somewhat shelly and porous lime deposit. The open cavities sometimes have a depth of fifteen feet, and in them can be seen to advantage the character of the travertine. It would appear that the springs which carried the lime, magnesia, iron, etc., which were deposited to form the ridges, were generally arranged along parallel fissures in the underlying rock. In places it would seem that as the ridges were built up the central fissure grew wider, and the deposition terminated with the filling of this central cavity by travertine. In nearly all cases the travertine was formed in the vertical fissure, while the shelly layers of the lime adjoining were nearly level, sloping off on either side. One mole is still in process of formation. Numerous springs, varying in temperature from lukewarm to boiling, are scattered irregularly over the spaces between the ridges, but do not leave any deposits near their orifices, the lime and magnesia in the latter case not being precipitated immediately on reaching the surface. The outer portions of a number of the moles have been partly worn away. In one or two there are considerable quantities of magnesia and soda; the travertine in the center, being much harder, is not so easily eroded. The extent of the travertine and onyx is evidently considerable, insufficient work has yet been done to show the depth to which they reach. In places it would appear that it must be more than fifty feet. The great beauty of the travertine found here will undoubtedly bring a large amount of it into use. The California Travertine and Onyx Company, of Bridgeport, is developing the property.

RECENT TRAVERTINE DEPOSIT, MONO COUNTY.

MAIN FISSURE OF THE TRAVERTINE DEPOSIT.

A TWENTY-TWO-TON Armstrong rifle throws a solid shot twelve miles, much farther than its report can be heard. At its highest point, for this extreme range, the shot would be over three miles above the earth's surface.

English Comment.

The London *Mining Journal*, in its issue of April 20th, has a fair article on "Gold-Mining Progress in California," its leading editorial. It is conservative in tone. In the course of the article it says: "Considerable attention is being concentrated upon the mineral wealth of California, and renewed activity is the consequence. * * * * No item contributing of late to the prosperity of the mining industry is more significant and conspicuous than the evidence continually forthcoming, both verbal and written, respecting the remarkable gold richness of California. Experts—well-known and reliable engineers—who have recently visited the country, speak in glowing terms of its wealth; of the facilities that exist for working, and of the brilliant future that is in store for it, provided that the opportunity now presented is taken advantage of. Of the latter alone they are doubtful, for effort and capital are being concentrated too much in one direction, to the disadvantage of other fields that are worthy of their attention. The interest in gold mining in California has markedly increased during the past two years, very likely due to the unexampled depression which has characterized silver mining. It is interesting, as well as significant, to note that the three properties now producing the largest amount of gold per annum are all mines which were abandoned some years ago, when the conditions were different; but, being thoroughly equipped and exploited by the reinvestment of capital, were reopened and successfully worked. As is well known, the gold is the product largely of quartz mines, and within recent years the cost in both mining and milling has been greatly reduced. The consequence is that gold mines which could not formerly be profitably operated are now worked at a profit. Speaking of quartz mining, evidence proves demonstrably that it is in a better condition than it ever has been. The speculative features have been to a great extent eliminated and careful business methods adopted, resulting in a more profitable work and greater confidence of investors. The annual gold production of California has remained for some years between twelve and thirteen millions of dollars; but, of late, in consequence of the renewed activity of which we have spoken, the output has been materially enlarged. Many old properties have been reopened and new ones developed. * * * * California seems to possess all essentials for the profitable prosecution of the mining industry, except capital. Through lack of the latter many promising claims are lying idle. Nevertheless, there is a faint hope that even this vital necessity will be rectified, but, unfortunately, it cannot be prophesied that it will be remedied in the near future."

TABLE OF CONTENTS.

ILLUSTRATIONS.—Recent Travertine Deposit, Mono County; Main Fissure of the Travertine Deposit, 289. Floating Island in Emerald Bay, Lake Tahoe, California, 292. Pelton Wheel Driving Air Compressor, 293. Pohle Air Lift Pump, 294.

EDITORIALS.—Travertine; English Comment, 289. Progress of the Work; Lateral Rights; Unfairly Stated; It Is Hoped Not; Miscellaneous, 290.

SCIENTIFIC PROGRESS.—A Difference in Custom; Sulphur, a Compound of Carbon, Hydrogen and Oxygen; The Gas Engine and the Steam Engine Joined, 295.

MECHANICAL PROGRESS.—Does Away With the Dead Center; Perfect Belt Transmission; Faulty Application of Pulleys and Belts; The Use of Low-Water Alarms, 295.

ELECTRIC PROGRESS.—Miscellaneous Notes. 296.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 298-99.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 302.

MISCELLANEOUS.—Concentrates, 291. Our Largest Lake; The Man from Cassiar; Co-operative Contract System Successful, 292. South African Gold Mines; Removing Cinders; Pelton Wheel Driving Air Compressor, 293. Pohle Air Lift Pump; The Mines of Nevada; Coast Industrial Notes, 294. Oil Fuel for Locomotives; The Useful Donkey, 300. Notices of Recent Patents, 302.

AMADOR COUNTY is interested in the preseut project of working the 20,000 tons of tailings at the Drytown Sulphuret Works by a "modification of the cyauide process." The tailings are credited with an average value of $8 per ton. The works, which have a daily capacity of 75 tons, were expected to start this week, and the result may be of interest to owners of similar dumps in other places.

THE *Examiner* of this city gives just prominence to a recent statement in "Printers' Ink," the great journal for advertisers, published in New York City. "Printers' Ink" is to the advertising professiou in this country what the MINING AND SCIENTIFIC PRESS is to the field it occupies. During the past week this paper is iu receipt of three letters from the proprietors of "Printers' Ink." In one tbe statemeut is made that this paper is credited with a higher circulation rating than any other devoted to mining in the State; in another it is stated that this paper is similarly honored in the realm of science, aud in the third it is averred that the same superior staudard is accorded it in the list of journals devoted to electricity. Each of these three letters was unsolicited. The distinction thus conferred is gratifying to know, but the resultant gratification would be enhanced by the receipt of a further statement from the publishers of that reliable authority that the MINING AND SCIENTIFIC PRESS does not measure its bouudary nor the area of the fields it fills by ordinary State lines, but that, with one exceptiou, it claims in its chosen sphere a larger circulation thau any of its contemporaries or competitors. This is not said boastfully nor with any other than the most kindly and courteous feeling toward its able coutemporaries and energetic competitors, but is simply a statement of the truth. Few, iudeed, are the mining men on this contiuent, wherever they may be, who do not weekly see this paper.

Unfairly Stated.

"I am for restoring silver," says Gen. P. W. Hardin, "to where our fathers had it—free and unlimited coinage." If we restored silver to where our fathers had it, we should expel it from the country. Up to "the crime of 1873," as Gen. Hardin terms it, only about $8,000,000 of silver had been coined in this country, aud for nearly forty years these were so scarce that they were rarely seen except as "pocket pieces" and curiosities.—*Louisville Courier-Journal.*

The *Courier-Journal* is again unfortunate in its statements. The "$8,000,000 of silver" it refers to above were eight million silver dollars. In addition, there were coined $97,000,000 in smaller silver coins, a total of $105,000,000 silver coinage in the period stated. Probably the *Courier-Journal* does not misstate inteutionally, but a California journal which attempted to deliberately aud continually argue and reply iu such a mauner would be told that it was lying.

Progress of the Work.

Mr. A. H. Ricketts, who was recently sent to Washington, D. C., by the executive committee of the California Miners' Associatiou to represent the case of the miners of this State, has returned. One of the first things he noticed at the seat of the National Government was that few, if auy, of the officials knew anything about mining, or had any practical knowledge of the merits of the case, either way. They found it difficult to understand that one-half of a section of land could be mineral and the remainder something else. Drift, hydraulic or quartz miniug were to them unknown terms. It became his province and his purpose to afford some primary information on this subject, and he believes that in this as in other regards the result of his mission will be beneficial. The second uoticeable feature was the evidently superior privileges that the agents of the railroad have there. Continuous residence, long acquaintance and familiarity with the officials have, of course, much to do with that. Mr. Ricketts found upon investigation in Secretary Hoke Smith's office that there was considerable celerity in the approval of supplementary lists. Indeed, it seemed as if the wheels of departmental action had been greased. The Secretary had assured Congressman Caminetti that pending investigation he would suspend further issuance of patents to mineral land grants to the railroads, but examination of the records showed that on April 20th he had formally approved the supplemeutal list of 93,000 acres at the Roseburg office of the S. P. Co., aud on the following day had approved a Central Pacific list embracing three times as much. Four other clear lists had been also approved, all in a space of four weeks, though ordinarily it takes several months to get even one list approved. This seemed to be an extraordinary case. It is possible that the Secretary of the Interior has, in those cases, been imposed upon by some of his subordinates. Mr. Ricketts wasted little time upon H. Lamoreux, General Commissioner of the Land Office, who seems to be merely a willing tool of the railroad company's resident attorneys and satellites, but, after a brief and breezy interview with the Commissioner, he sought the presence of the Secretary of the Interior, and entered a formal protest against such issuance of patents of disputed land to the railroad company. Mr. Hoke Smith had no explanation to offer as to why he broke his promise to Congressman Camiuetti, nor was any explanation asked.

The uext day Mr. Ricketts called upon President Cleveland. To his excellency he recited the main facts, reviewing all that had transpired since the first publication in the MINING AND SCIENTIFIC PRESS of the rules promulgated on the 9th of July '94, and brought up all with which our readers are so familiar, including the swift and stealthy actiou of the company, the unwarranted basis of its claims, tbe apparent collusion iu the Government offices, and laid special stress upon the legal point that in in March, 1879, in a law passed by Congress, it was specifically stated that the Director of the Geological Survey should classify the public lands and examine their geological structure and mineral resources, and that a fair interpretatiou of such law would cause that Government bureau to do all that is designed by the Idaho-Montana act which passed last December, or is contemplated by the California act which did not pass in the closing hours of the 53rd Congress. He argued that the carrying out of that law, with the famous decision of the Supreme Court of the United States last August in the Barden case in Montana, would render furtber legislation on the matter unnecessary so far as California was concerned, and so work as to give justice to the miners or a chance to them to secure justice under its workings. He asked the President to interpose his power in their behalf by ordering the immediate suspension of all proceediugs iu the office of the Secretary of the Interior toward allowing the railroad companies to absorb the public domaiu till Congress met or till some competent tribunal passed upon the points raised and the matters at issue.

The President gave him his undivided attention, seemed surprised at much that he was told, and promised to look into it and help, at the same time asking Mr. Ricketts to remain in Washington to speak further on any point that needed explanation. Three days after—last Saturday—he got the following letter:

A. H. Ricketts—DEAR SIR: I have had an interview with the Secretary of the Interior, and your statement has been referred to him. Of course I do not know what action we can or ought to take on the premises. I merely write to say that there seems to be no necessity of your remaining here to make further presentation of the matter. I do not know how far the patenting process has progressed. It may be that it has reached such a stage as to preclude interruptiou, irrespective of other considerations involved. Yours truly,

GROVER CLEVELAND.

This epistle is no more satisfactory than other famous epistles from its author on equally famous subjects. In it he evinces an intention to leave the matter entirely to the Secretary of the Interior. Whatever further injustice is permitted by the Administration caunot be because of lack of knowledge of the facts. Every official from the President down to the doorkeeper fully understands the situation. Meanwhile tbe work will go on, and persistent effort maintained to secure justice for the California miner and prevent the absorption by the railroad corporations of the mineral area of the commonwealth.

Lateral Rights.

In the United States District Court of Colorado, in the Del Monte case, Judge Hallett, in his decision, gives a definition of the lateral right pertaining to an apex crossing a side and end line, incidentally touching upon the inapplicability of the Amy-Silversmith case to this state of facts. He says:

"It is true that in the Flagstaff case, and recently in the Amy-Silversmith case, the Supreme Court declared that the end lines of a location shall be end lines wheuever the lode ou its strike crosses such lines; but these decisions do not affirm that all end liues of a location crossed by a lode on its strike shall be end lines. The most that can be deduced from them is that opposite lines parallel to each other when crossed by the lode shall be eud lines. The case presented is not within the principle of these decisions. We have a lode extendiug on its strike on the general course of the location and within tne side lines a distance of 1070 feet. It is couceded that the south end line of the location is well placed, aud all parts of the lode covered by the location are within the end lines as fixed by the locator. The difficulty arises from the circumstance that the location extends in a northerly direction about 820 feet beyond the point where the lode diverges from the side line. No reason is perceived for saying that this mistake in the length of the location should defeat the right to follow the dip of the vein outside of the locatiou. It is said that we cannot make a new end line at the point of divergence or elsewhere, because the court cannot make a new location nor in any way change that made by the parties. This, however, is not necessary. We can keep within the end lines fixed by the locator in respect to any extra-lateral right that may be recognized without drawing any line, and if there be magic in the word 'line' it will be better not to use it.

"The case is not entirely different when the lode intersects oue end line and not the other, but keeps within the location for a considerable distance. In that case, as in the accepted case of a lode traversing the location from end to end, the locator ought to be allowed to follow his lode into adjoining territory so far as he may within his lines, and so far as he holds the outcrop in his location. Upon this construction of the statute respondent is entitled to so much of the lode upon its dip as lies between the 'south compromise line' and the point of divergence of the apex of the vein from the location."

It Is Hoped Not.

The gold-mining craze is certain to invade New York in the course of sixty or ninety days. Millions of dollars will be made out of such speculations, and the furor among all classes will be the greatest ever known.—*New York Town Topics.*

It is to be sincerely hoped that such a "craze" will not ensue. Nothing is further from legitimate mining, but nothing so hurts a mining area included in its operations. There are millions to be made by careful investments in gold mines and judicious, economical management of their workings, but only by the slow, ordinary commercial routine attending any other legitimate business. Any one who goes into it on a different proposition is a gambler, and a gambler's fate awaits him.

Concentrates.

Fifty men are now at work in the Willow Creek, Idaho, mining camp.

The April clean-up of the Bonanza, Baker Co., Oregon, ten-stamp mill was $20,000.

The May dividend of the Morning Star mine of Iowa Hill, Placer county, is $4 per share.

The Silver Queen mine, sixty miles south of Kingman, Arizona, is to be sold this month to eastern men.

The Everett, Wash., smelter has resumed operations. There is an accumulation of ore ready for treatment.

It is reported that H. P. Stow of Forbestown, has prohibited the men who work in the Gold Bank mine from gambling.

The April pay-roll of the Comstock mining and milling companies amounted to $76,603.66—about $1000 higher than that of March.

It is reported from DeLamar, Nev., that the mill has been shut down because of a scarcity of water, and sixty men laid off.

"Quartz Johnson," a well known old-timer, who came to Coulterville in '46, died there last Saturday in the 80th year of his age.

Union miners in Wardner, Idaho, have denounced the A. P. A. and refuse to allow members of that body to work in the mines there.

A three-stamp battery, run by an 8-H. P. gasoline engine, is now at the Rose Hill mine, Nevada Co., the forerunner of a more pretentious plant.

Lead has been found in the sandstone in Salina canyon, Utah. Silver was found in paying quantities in sandstone in Utah twenty years ago.

Manager Dern of the Mercur, Utah, mine has about determined to build a plant in Salt Lake of sufficient capacity to handle the Mercur cyanides.

The Oro Fino mine, three miles from Nevada City, is being developed anew, has been renamed the Stanford, and will have a ten-stamp mill this month.

Geo. Mainhart has a bond on the Fortuna mine, near Nevada City, and is having it pumped out preparatory to developing what is deemed a valuable property.

T. J. Nichols, treasurer of the Placer County Miners' Association, informs the Colfax *Sentinel* that contributions to the miners' fund in that county aggregate over $1000.

The time for filing protests with the Land Office at Sacramento against the issuing of patents to the railroad company for lands which are mineral, expires to-day.

It is claimed that $60,000 has been spent on the Hocumac mines located on "Old Baldy," Ontario, San Bernardino County. Omaha capitalists are pushing developments.

A man named Grossmann, who claims to be a mining expert, is under arrest at Reno, Nev., charged with conveying fictitious deeds to mining property in the Pine Nut district.

The only mine in Pioche, Nevada, now in operation is the Yuba, which is being worked under lease by Lloyd & Swindler, and is producing some ore that will stand shipment.

Twenty men left Selma, Fresno Co., this week for Alaska, under the leadership of F. Deesy, who claims to have authentic information of the existence of placer mines at Cook's Inlet.

The Finch Mining and Dredging Company, working on the Fraser, five miles north of Lytton, B. C., are reported to be making $20 an hour, the cost of operating the plant being $20 a day.

The Virginia Mining and Milling Company has incorporated in Los Angeles; capital stock, $500,000; J. M. Witmer, H. H. Russell, H. F. Hartzell, A. W. Davis, C. G. Van Fleet, directors.

Thirty men are employed at the Mt. Jackson quicksilver mine, fourteen miles from Healdsburg, Sonoma Co. There are 250 tons cinnabar ore on the dump. The April output was 187 flasks.

The Mountain Chief Mining Company has incorporated at Oroville, Butte Co.: capital stock, $8000; directors, G. M. Graysen, Jr., C. L. Donahoe, J. F. Sersamons, W. H. Sale and J. H. Graves.

Though there is still plenty of gold in the mountains, the Mariposa *Gazette* thinks that the prospector who works but an hour a day and plays pedro the rest of the time is not going to find much of it.

The Central Pacific R. R. Co. advertises in the Nevada *Herald*, of the 2d inst., that "Lands covered by actual mining claims, which are being operated as mines, will be relinquished without consideration."

After a dormancy of nearly two years, the Hunter mine at Mullan, Idaho, again prepared to resume operations but the customary labor troubles in that region compelled the superintendent to abandon the project.

The Eureka Consolidated will now go ahead and let some new contracts. The suits of Keyes and Arents against the company, which were on appeal at Washington, D. C., have been decided in favor of the company.

The Garfield mine at Atlantic City, Idaho, is now turning out $150 a day in gold, working only during the day-time. A new six-foot vein has been struck, which is one of the best ore bodies ever found in that famous mine.

The Inter-Ocean Mining Company, capital stock $500,000, has filed articles of incorporation at Rawlins, Wyoming. The trustees are W. Hatton, F. Moore, W. J. Cran, C. C. Marshall, J. H. Stewart, S. S. Blanchard, F. Menking.

The *Courier* says the Montgomery gold mines in southern Nye Co., Nevada, are looking well and another Huntington mill is to be erected. Thirty new tents have been pitched in the district in the last month by prospectors and miners.

W. C. D. Body has been awarded the contract to erect the ten additional stamps at the W. Y. O. D. mine, Grass Valley. No new structure will be erected, but the present mill will be widened. The contract for machinery has not yet been let.

Large bodies of elatente, ozocente and gilsenite are reported discovered in eastern Utah and western Colorado. Denver men are credited with intent "to open up the mines and commence the manufacture of rubber goods and candles."

The Nimshew Gold Mining Company has incorporated in Butte county; principal place of business, San Francisco; capital stock, $100,000, $5000 actually subscribed; directors, J. M. Wells, G. R. Fletcher, J. R. Davidson, W. B. Hamilton and D. Gutmann.

Forty-six companies mining on the Witwatersrand employ 2345 stamps to mill on an average 262,897 tons of "banket" per month. The average quantity of stone crushed per stamp per diem is stated to be 4.23 tons, and the gold yield 8.91 dwt. per ton, valued at £1 12s 1d.

Extensive developments on the Sunnyside and Beckwith Consolidated Gravel mines on the McRea ridge, Plumas county, give good promise of satisfactory yield. That part of Plumas county is a promising field for moneyed men to develop rich gravel and quartz mines.

A shipment of $61,689 in gold was received this week from the Alaska-Treadwell mine, representing the run of the mill for thirty days, during which 23,039 tons of ore were worked, averaging $2.68 per ton, and 243 tons sulphurets were treated. The gross expenses in April were $26,782.

The Basin, Montana, *Times* dejectedly says: "If ever the placer miners looked down in the mouth it is in the present year of our Lord. No water, no diggin's. The hills are about bare of snow, with prospects of a mighty short season's run for these gray-bearded old grizzlies of the Rockies."

The first Northern Pacific patent to lieu lands ever received in that district arrived at Spokane, Wash., this week. It covers 16,192 acres, nearly all of which is in Lincoln county, and much of which, it is said, is occupied by men who have delayed filing contests, thinking there would be "plenty of time."

Last fall a man named Springer gave another named Lewis verbal permission to sell a Trail Creek claim, keeping all he got over $1000. After some time Lewis got $1500, but Springer refused to pass the title, as the claim would now bring $50,000. The county court has held that Springer must make the transfer.

The men who engage California miners to take charge of important South African enterprises pay princely salaries. Harry Webb gets $15,000 per annum: R. H. Cavill $7500. Jno. Hays Hammond's $60,000 is as much as is paid the President of the United States and a justice of the Supreme Court of the United States.

The Calumet and Hecla, Mich., copper mine pays a $500,000 dividend to-day: this makes an aggregate of $41,850,000 cash dividends that great property has paid to date. The Tharsis copper mine, a European property, is another great dividend-payer. A $625,000 dividend was paid yesterday, being a total of $26,292,160 to date.

The Trinity County Miners' Association has raised in addition to previous donations $100 to second the efforts of the State Miners' Association in securing the mineral lands against the claims of the railroad. In addition to this, Hon. John McMurray went among the business men of Weaverville and obtained about $100 more.

The United States Census Bureau, in mining statistics, shows that the labor employed in the actual production of the precious metals averages $725 per year: the average output per man amounts to $1723 a year. Mining pays higher wages to the laborer and better profits to the employer than any other business carried on in the United States.

The Birkbeck Investment, Security and Savings Company of Toronto, has incorporated to mine in British Columbia. The Finch Mining Company, limited, of Pittsburg, Penn., has likewise incorporated; capital stock, $6,000. A new limited liability company is the Vancouver Gold and Silver Exploration and Concessions Company, of Vancouver; capital stock, $500,000.

The Mojave *Miner* hears that reorganization of the Mammoth Mining Company is in contemplation, and that the principal English stockholders are now on their way to this country for that purpose. The Mammoth is in Pinal county, and is one of the largest and richest gold mines in Arizona. The new organization will expend about $200,000 in improvements, among which will be the removal of the mill from the San Pedro river to the mine and the increase of its capacity to 100 stamps.

Sam'l Collyer, of the Tacoma, Wash., Chamber of Commerce, sends the following statement of the Tacoma Smelting and Refining Co. for the month of April, 1895: Number of men employed, 61; pay-roll, $4,327.31; wood-choppers and teams, $680; total pay-roll, $5 007.31. Product: 2200 bars bullion, weighing 227,508 pounds. Contents: 1315.04 ounces gold at $20.67—$27,181.87; 21,959.61 ounces silver at 66¼ cents —$14,603.14; 225,913 pounds lead at $2.95 per cwt.—$6664.44; total, $48,449.45.

A. R. Hammond—who has been retained as consulting engineer to the Franco Syndicate, started by Parisian financiers with £400,000 capital, half of which was subscribed in London, to explore and develop large concessions obtained from the Portuguese Government from the Guenene to the Congo, eastward to the head-waters of the Zambesi on the borders of the Barotseland, South Africa,—is organizing an expedition to examine its mineral resources, and the practicability of constructing a light railway from the coast to the Upper Zambesi regions.

The West Le Roi & Josie Consolidated Mining Company has been incorporated at Spokane, Wash.; capital stock, $500,000. The incorporators are G. H. Casey, C. Griffith, D. Holzman, S. I. Silverman, J. M. Burke, J. B. Jones, R. Thompson, H. M. Stephens. The primary object is to carry on a mining business in the Trail Creek District, British Columbia. The Great Western Mining Company, which recently incorporated there, has organized. The officers are L. Bertonneau, president; J. B. Jones, vice-president; H. M. Stephens, secretary and treasurer, M. Burke, manager.

Under date of the 1st, Stephen Barton, who has charge of the canal work now in construction in Kern Co., writes from Kernville, that the company engaged in constructing the electric canal under his charge is incorporating. The company name has not been yet selected. The works will be near Keysville; the postoffice address for the present will be Kernville. The men engaged in this enterprise are mainly residents of Chicago. "The work, so far, looks to a canal sixty-five feet wide and five feet deep, and is expected to have a carrying capacity of 700 cubic feet per second and a fall of 350 feet."

The Ibex, Utah, mine was attached last week for an unpaid note of $10,000, which was followed by other claims. A Salt Lake man who claims to be posted says that the mine had produced $350,000 worth of ore since its purchase in 1894; that but $50,000 had been paid on the purchase price, and that the smelter involved an expenditure of $80,000, which makes a total of $130,000. This leaves at least $220,000 to cover the cost of operating the mine. A plant which has cost but $130,000 and has produced $350,000 in the time it has been held by the owners is not a bad proposition, and somebody seems to have made money out of it.

The *Record-Union* is now after the quartz miners, and says that the quartz grit coming from the stamp mills "is the most injurious form of debris." First, it was hydraulic mining that incurred the *Record-Union's* displeasure; then drift mining came under the ban, and now the poor quartz miners are excommunicated. With butter at ten cents a pound, the man who makes two blades of grass grow where but one grew before is a public benefactor; with gold at $20.67 an ounce, the man who adds an ounce or a ton of it to the commonwealth is a villain. By its malicious exaggeration and manifest unfairness the *Record-Union* has destroyed its influence and neutralized the effect of its assertions.

The Oregon & California Railroad Company has applied for patent to another lot of land in southern Oregon, aggregating about 12,000 acres. Some of these lands are situated in Douglas county, more in the extreme western part of Jackson county. Mineral land is included and those interested in that section should investigate the descriptions carefully. The lists were filed with the officers of the Roseburg land office April 23d, and sixty days from that date are allowed for the filing of protests or contests against the claim of the railroad company on the grounds that the land is more valuable for mineral than for agricultural purposes. These protests should be filed with the Roseburg land office officials.

Prospectors along the Columbia have thought that if they could only cross over on the reservation they could pan out gold, and some have tried it, but all have recently given up the job. When the Indians found that the Boston men were mining on their side of the river they at once ordered them away. All kinds of barters and propositions made by the white men to remain were dismissed without ceremony by Siwashes, and the whites bad to vamoose. One of the miners is said to have been so provoked upon being driven across the river that he secured an old needle gun and took a shot across the river at the first Siwash he saw. Now the Indians are worked up and threaten to shoot anybody found trespassing on the reservation.

W. G. Riffenbero, of San Diego, is about ready to put in operation his plan for placer mining in the Colorado river, and will begin at Temple Bar. He has built two catamarans which he will anchor in mid-stream by steel cables up and down the river so that the boats will remain stationary. Two wheels, twenty feet in diameter and with a twenty foot breast each, will be placed between these catamarans and attached to the them, so that the current will revolve them. These wheels are expected to develop 140-horse power. Located on the catamarans will be two pumps, operated by the wheels, to irrigate. The ropes will be so adjusted that they will permit of a twenty foot rise in the river without any inconvenience to the boats or wheels, and appliances are also provided for protecting the boats and wheels from drift, and in case of extraordinary high water, for swinging them into the shore. The boats are built, the two pumps are at Kingman and will be placed in position this week. The plant will cost $15,000, and if successful, this amount will soon be realized from washing gold out of the gravel on Temple Bar.

The Sutro Tunnel—"The Comstock Tunnel Company," has an income of $2800 per month; its monthly expenses are about one-half that. The recent change in the ownership of that famous bore, which, with its branches drains the Comstock to the depth of 1600 feet, encourages the belief that active mining and development work will be pushed. Under the rule of the late owners little was done except to keep up repairs on the new tunnel. The new owners will, it is said, put the property in good condition, clean out and repair the branches that run north and south along the front of the lode, when they will hold in command all the Comstock mines from the level of the tunnel to the surface, and all the unexplored "west country" lying back of the lode. It is understood to be the intention of the new owners to encourage the extraction of the numerous deposits of low-grade ores known to exist at several points along the lode in the old levels between the tunnel level and the surface. As in working from below upward, every pound of rock and ore excavated will descend to the tunnel level by force of gravity, exploration and all other work may be done more rapidly and cheaply than is now being done by working downward and hoisting both ore and waste rock by steam power. In working upward there need be but little handling of the material excavated, as chutes can carry the ore and rock down to the cars plying in the tunnel.

It is estimated that the Transvaal mines lose £300,000 a year by the inability to treat slimes. How to recover this by profitable treatment is a question now discussed on the Randt, and "developments of distinct importance for gold mining are promised in the attention directed to the solution of this problem. In one quarter the whole merits of dry crushing to prevent slimes and direct cyanidation are being debated, while, in another, practical efforts are attempted to separately deal with slimes, and thus avoid the interference with existing plants which the first proposal would involve." It is claimed that, with rich slimes containing about 7dwt. of gold to the ton, successful treatment has already been achieved. By means of disintegration and subsequent pressure, 98% of gold has been obtained at a cost of 10s. per ton. The bulk of gold slimes, however, does not carry more than 3dwt or 4dwt to the ton, and obviously it would not pay to deal with them in this manner. It cannot be said that any actual working success has attended the experiments with poorer slimes; but several processes have appeared so far promising of practical results that trial plants have been erected at different South African gold mines. One of these aims at improving the precipitation of gold from dilute solution, which is sought to be effected by preserving the chemical purity of the zinc, and by the addition of an electro-negative element.

Our Largest Lake.

Herewith is illustrated Lake Tahoe—that greatest of all the mountain lakes of the Sierra Nevada. The lake occupies an elevated valley at a point where this mountain system divides into two ranges. It is, as it were, engulfed between two lofty and nearly parallel ridges lying to the east and west of the lake. As the higher range is on the west, the lake belongs to the eastern slope of the Sierra Nevada. The boundary between California and Nevada corners in the center of the lake, and this point is not changed, though recent surveys have inclined the southerly extension of the line eastward, so that California gets more territory.

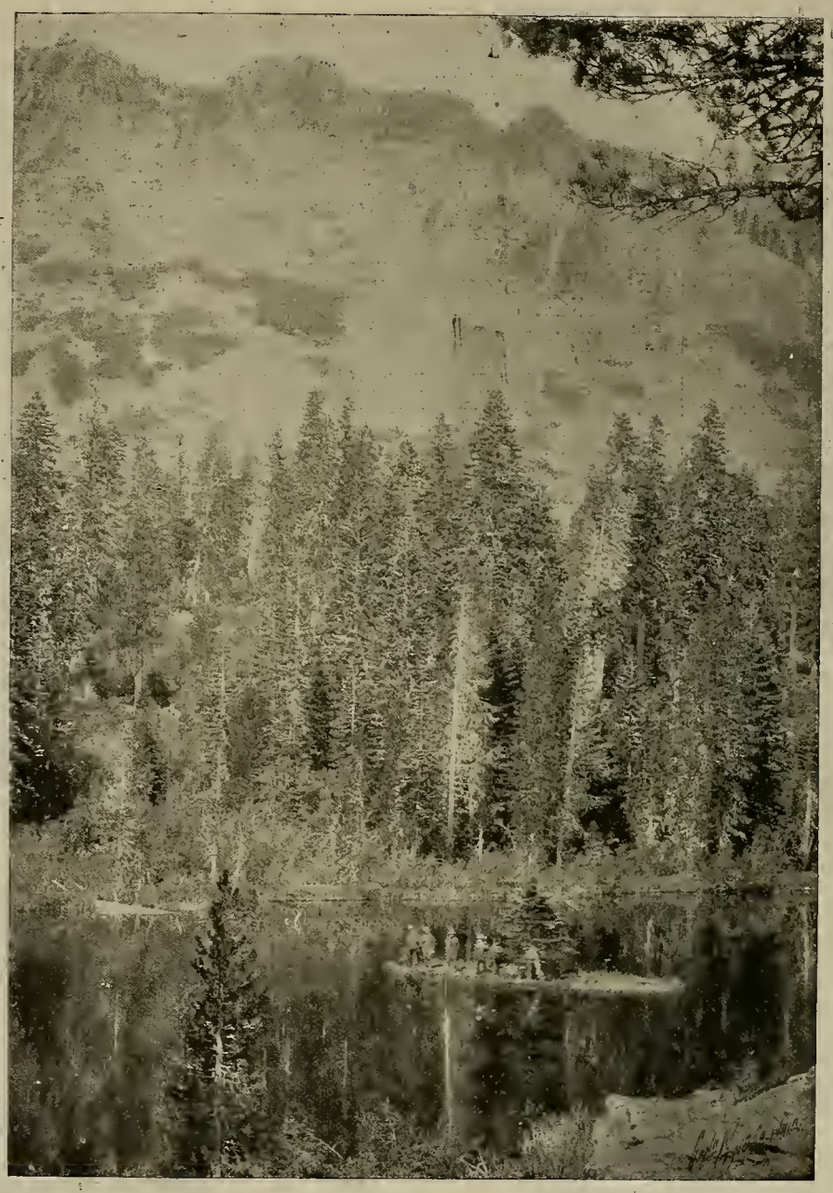
Lake Tahoe is over twenty-one miles in its greatest length and twelve miles in its greatest width; and calculating irregularities of outline, the water surface is about 200 square miles. It derives its waters from a watershed of 500 square miles and more than 100 affluents of various capacities, deriving their waters from the amphitheater of snow-clad mountains which rise on all sides from 7000 to 12,000 feet. The only outlet from the lake is Truckee river, which carries the surplus waters from a point on its northwestern shore, out through a gorge to the plains of Nevada and thence to Pyramid lake.

Lake Tahoe was first seen by Fremont, after information of its existence from the Indians. It has had various names. By statute of California it is Lake Bigler, but usage has now fully established the name Tahoe, which is said to be a Washoe Indian word meaning "Big Water" or "Deep Water," though some claim that the word simply means "Fish Lake."

Tahoe impresses all visitors as a grand piece of water. Its great size, when one considers its lofty perch amid the mountain summits, is profoundly impressive. The depth of its waters also strike one with awe. Local declarations of its depth, in connection with the fact that sunken bodies do not rise, and the speed with which dangerous squalls arise without warning—all combine to make the visitor shudder while he admires. The depth of the water is usually exaggerated, although the demonstrated depth of 1645 feet, established by Dr. John Leconte, makes it deeper than the profoundest of the Swiss lakes.

The charms of Tahoe are beyond enumeration. The peculiar hues of its waters at places of varying depth are entrancing. The coolness and purity of its water at all points are notable and it is not wonderful that it should stand as the ideal source of water supplies for the cities of central California, when population and wealth shall justify the necessary expenditure.

Our engraving gives a glimpse of one of the most popular arms of the lake, known as Emerald Bay, situated near its southwest corner. This bay has a charming green hue to its water. It is surrounded by a fringe of timber, while the rocky and often snow-mantled mountain sides beyond the timber rise in majestic forms and dimensions. The picture shows only a part of Emerald Bay. It has wider waters and larger islands, but the photographer has chosen a point where an object of much interest is in sight—a floating island sustaining tree growth and capable of sustaining quite a cargo of tourists, as the picture shows.



FLOATING ISLAND IN EMERALD BAY, LAKE TAHOE, CALIFORNIA.

THE work of weighing the mails in order to settle upon the amounts to be paid to railway companies for their transportation is finished in the middle section. The weighing began on April 1 and terminated on the 30th. For the purpose of these weighings the whole country is divided into four districts, corresponding nearly to the east, south, middle and western sections of the country. The mails of but one section are weighed each year, and the results obtained are used as a basis for computation for four years, until the turn of the section comes around again. The weighing is done either in the spring or the fall, as the winter mails are unduly heavy and in summer unduly light. When the work is finished contracts are made with the roads. The Government pays $42.75 per annum for carrying 200 pounds of mail daily per mile of route. For 500 pounds $64.12 is paid; for 1000 pounds $85.50, and so on. Land-grant railroads receive 20 per cent less than these rates.

The Man from Cassiar.

St. Peter (to applicant)—You say that while on earth you mined in the Cassiar. Now tell me, did you ever lie to your fellow beings about that country?

Applicant—No, saint, I have always told the truth.

St. Peter—You never told that you took out a hundred ounces to the pan, that you used frozen quicksilver for bullets, that smoke clung to the branches of trees in great frozen clouds, and when you addressed your partner he had to wait until spring for the sound to thaw out?

Applicant—No, saint, I never told such things.

St. Peter—You didn't, eh? Well, then, you're lying to me now, for if you never told those things you never came from the Cassiar. Here, Paul, take this man below.—Alaska Mining Record.

IT IS ASTONISHING how very low the cost of producing steel ingots and rails, in the item of labor, has now fallen, owing to the economies effected in the manner of labor-saving machinery and improved methods of working. It will hardly be believed that in Great Britain the labor cost of producing a ton of steel ingots, whether at Bessemer converters or open-hearth furnaces, does not exceed 4s. per ton, and in the best practice is probably not much over 3s. The chief items are pig, steel, scrap; coal and ferro-manganese—the total cost varying from £3 6s. to £3 10s. per ton. In the United States, although wages are nominally higher, the cost is not greatly different.—London Iron and Coal Trades Review.

THE waters of North America, which means the Gulf of Mexico, the two great oceans and the rivers, creeks and lakes, are stocked with 1800 different varieties of fish. Of the above number 500 are peculiar to the Pacific and about 600 to the rivers, creeks and lakes.

Co-operative Contract System Successful.

On several occasions the co-operative contract system of doing shop work, first described by an Eastern exchange, has been mentioned in these columns. This is a system which is said to be far superior to the day-work plan, the purely piece-work method, or any of the various schemes proposed for profit sharing, between the employer and the employe. This system has been established in one of the largest electrical manufacturing establishments in the country and its operations are explained by an exchange. When it was decided that all the men should work together and share in the profits the first thing necessary was to fix a basis. In a certain department, prior to the introduction of the new system, each man was rated at a certain sum per hour, supposed to be adjusted according to merit. Taking that rating and the number of hours worked during the week, as a basis, the distribution was made as follows: A. is rated at 25 cents per hour, B. 20. A. works 60 hours, B. 50. Their earnings, according to rate, being $15 and $10, respectively; a total of $25. The product of their labor for that week, according to the price paid for it, amounted to $30, leaving a profit of $5. As A. earned 60 per cent of the $25, he should be entitled to 60 per cent of the profits, or $3, which, added to the $15, makes his entire wages $18. And as B.'s earnings only show 40 per cent he can claim only 40 per cent of the profits, or $2, making his total for the week $12.

The gentleman, in describing the results of the system, says that no more equitable system of distribution could be imagined. Gangs were organized throughout the works, each with its leader or gang boss, who was rated slightly higher than the others. A co-operative gang unloaded the raw material from the cars, another made the packing cases for the finished product, another packed it into the cases ready for shipment, and still another placed it on the cars, and throughout all the different departments, where the requirements demand it, gangs were organized, and, in fact, some places where the requirements did not demand it. For instance, engines were built co-operatively, although a price was recorded for the necessary operations on each separate part; all completed parts being reported by operations, and credited to the gang, instead of the individual.

After a thorough test of the system, the gentleman referred to expresses the opinion that an establishment conducted on the day-work plan cannot compete with one on piece-work, and that the majority of failures in industrial lines throughout the country may be attributed to the day-work system. We give the statements made in the foregoing because any plan by which it is claimed that the relations between labor and capital can be made more harmonious should receive attention.—American Manufacturer.

BUSINESS never was in a condition to suit everybody. Legislation can't help the man who won't work, or the man who prefers to growl at every one else rather than make an honest, industrious effort himself. Legislation cannot prevent the daily demand for bread and butter, and the first duty of every man is to earn that. The times always improve when all hands go to work with a will, drop grumbling, hunting for the bright things of life rather than its unpleasant features.

TO TEST LEATHER BELTING, says an exchange, cut out a small piece of the belt and place it in vinegar. If the leather has been perfectly tanned and is therefore of good quality, it will remain immersed in vinegar even for several months without any other change than becoming a little darker in color. If it is not well impregnated with tanning, the fibers will promptly swell and after a short time be converted into a gelatinous mass.

SMALL LEAKS are not thought to amount to much, but an English engineer shows that a hole $\frac{1}{16}$-inch in diameter with a water pressure of only 45 pounds will get away with 648 gallons per day.

South African Gold Mines.

Johannesburg, South Africa, has about the same altitude as Eureka, Nevada—5600 feet. The Witwatersrandt reef and the coal deposits adjacent thereto make the place famous. Probably in no other mining camp in the world will so many mills, hoisting works, chlorination works and cyanide works be seen in such rapid succession and for so long a distance as upon the "Randt." Water for the works is obtained from springs, the mines and every available source, and is pumped into reservoirs and used over and over again until it is white with slime.

The Witwatersrandt gold-bearing reef seems to have been a basin formed by aqueous deposit and running in an easterly and westerly direction, cemented together and forming a conglomerate mass, locally termed "banket."

By some disturbance of nature, it was uplifted at an angle of about 35°, thus forming the present continuous lode or reef, broken by intrusive dykes of diorite or greenstone. Then there seems to have been a solfataric action from below which formed a vent in the parpus conglomerate, therein depositing sulphurets or sulphides of iron containing gold. In time, atmospheric action desulphurized and oxidized the iron, leaving some of the gold free, while some, no doubt, owes its free state to the precipitating action of iron. The country rocks of the Randt are chiefly sandstone cherts, shales, quartzite and granite, the conglomerate reef spoken of lying between these formations and averaging several feet in thickness. The Randt is a great low-grade proposition and is handled as such, and in the opinion of many is not worked so much for the actual profit in it as for the stock jobbing operations it affords.

But few of the mines are paying handsomely; others are paying not more than six or seven per cent upon their very large capital, while others are not paying at all, and, as an old miner remarks: "These companies have a way of making dividends appear all right on paper, but at the same time they are in debt to the bank and borrowing more money to go on with."

It is thought that the cyanide process, which extracts the gold from the tailings, is the salvation of the Randt, and that what dividends were paid come from this source. The Johannesburgers seem to think the mines will last forever, but, in the opinion of well-informed people, fifteen years will be a long life for these properties, worked as they are with the enormous force in actual operation, and then Johannesburg—the city of whirlwinds and dust storms—will meet the fate of many another mining camp, and houses, lots and machinery will be for sale cheap as dirt unless some unforeseen discovery should take place, which is hardly probable, as the country has been well prospected and taken up.

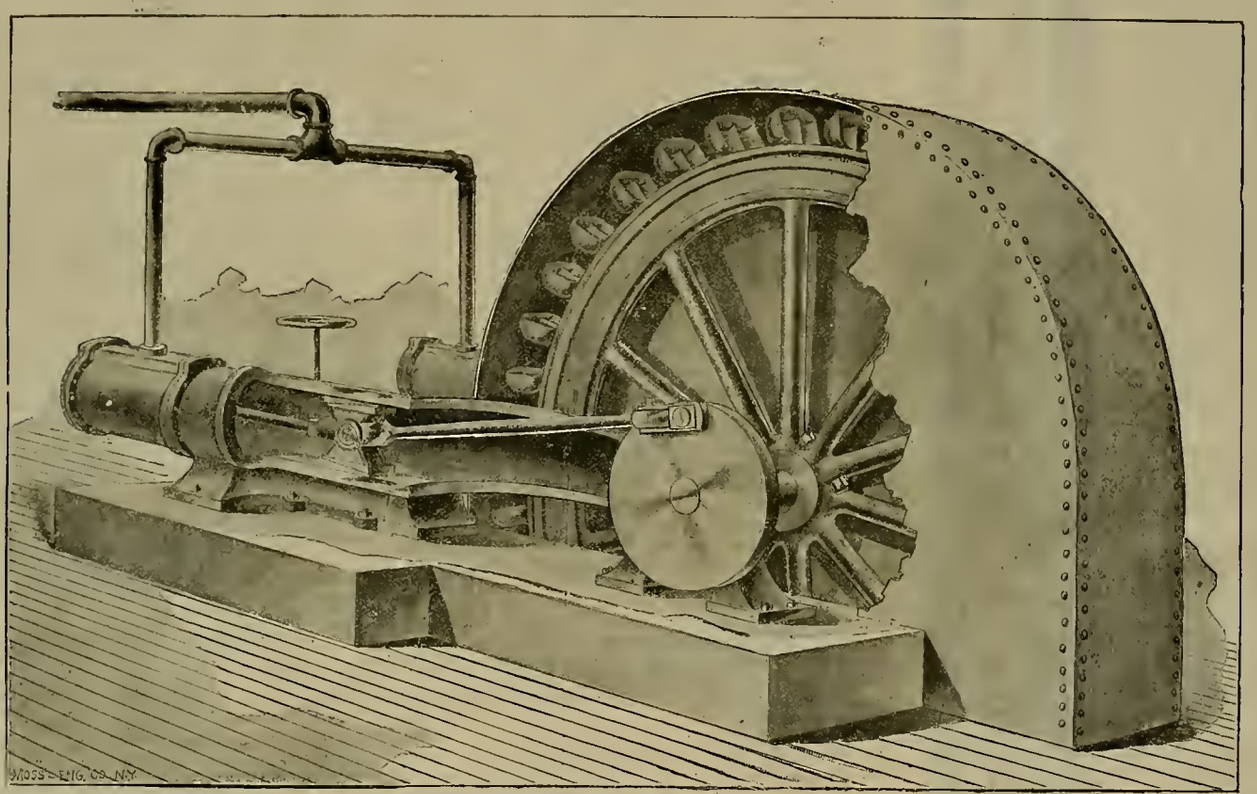
The mining laws of the country are stringent and peculiar, only 150 feet along the croppings by 400 feet in width being allowed; and as the reef dips at an angle of 35°, the holder of a claim would soon work out his mine, he not being permitted to follow the dip of the reef outside of his boundary lines. This state of affairs gave rise to what is known as the deep level claims, hence the whole country is pegged off as deep levels. Shafts are being sunk at some of these that will tap the reef at a depth, but it remains to be proven whether these deep level mines, as they are called, will be paying ventures.

A great problem arises in mining this reef, and that is the disposition of the tailings, there being no streams or other outlets for the immense amount of ore crushed. The tailings accumulate in immense piles of fine sand and slime, which, upon being dried, are taken up by the wind and blown in every direction. These tailings having passed through the cyanide solution are thoroughly impregnated with the deadly poison; and, when blown about, must certainly cause much cyanide poisoning by the inhalation of the fine dried particles held in suspension.

As an American would put it, the Boers seem to delight in getting a "lead pipe cinch" on the English, and hence have proceeded to tax everything from a mining claim to a needle. There is little which has escaped taxation, and this has been carried to such an outrageous extent that a most bitter feeling prevails among the people, whose capital, energy and enterprise have given prosperity to the Transvaal and elevated a little bankrupt republic to the dignity of a nation, having a surplus of £1,000,000 in the treasury.

British residents have been, by a recent law, prevented from obtaining the franchise and so excluded from all hope of getting redress by constitutional means. A monstrous law has been passed denying foreign residents the right of public meeting in the open air, and limiting indoor meetings to five persons. Such an attempt to stifle free speech and to prevent the public from the ventilation of grievances is despotism.

There are 3200 stamps in operation—about as many as in all California; their daily crushing is said to average four tons to the stamp—a bigger average than in our State. About seventy mines are in operation. It is expected to add 1000 stamps this year. A little over 2,000,000 ounces was produced in '94—the gold being worth £3 10s per ounce.



PELTON WHEEL DRIVING AIR COMPRESSOR.

Removing Cinders.

A hint on the removal of cinders and grits from the eye may not be amiss. The inner surface of the eyelids is ridged in such a way as to promote the moving of small particles towards the inner corner of the eyes, where the duct opens which leads to the nose. This is the particular fact on which this advice is based, and which also shows the extreme folly of the method usually adopted to extract cinders from the eye. This method is to double up the forefinger and rub it into the afflicted eye until it as red as a beet-root and suffused with tears. Some horrible contortions of the countenance are thrown in, as if to assist. Now, the only effect that such a course can have is to grind the cinder into the corrugations of the eyelid and keep it there for a week until the inflammation subsides. The proper way to do this is to catch up the eyelid by the skin and pull it away from the eye ball gently and repeatedly. This not only instantly relieves the pain, but promotes the shifting of the cinder in the right direction. In almost every case this will be found a speedy and painless remedy.

Pelton Wheel Driving Air Compressor.

The accompanying illustration shows a Rand duplex air compressor driven by a Pelton wheel mounted directly on the crank shaft of compressor. The wheel in the cut shown is 14 feet in diameter and works under a water head of 400 feet, this large diameter being required to give proper speed to the compressor.

The wheel, as will be observed, not only furnishes the motor power but is sufficiently heavy to serve as a balance wheel.

The advantages of attaching the wheels to the compressor shafts are: great economy of power, as well as in first cost, as also lessened cost of freight—a matter of first importance in machinery destined to places remote and difficult of access. The advantages so simple and efficient a connection afford are also manifest in the lessened cost of setting up the machinery, as well as in the absence of belt connections, the maintenance of which, with loss of power involved, are matters of the greatest importance in many mining localities, where every pound of water must be made to do its utmost duty.

This application of the Pelton wheel is made with equal facility to all forms of compressors, as well as blowers and many other classes of machinery, and in all cases where the head admits, the wheel can be made heavy enough to serve as a fly wheel, thus simplifying and cheapening still more this manner of applying power. Wheels in such cases may be made of any size, ranging from 6 up to 12 or 16 feet in diameter, as may be necessary to give proper speed to the machinery they are designed to run, suiting the buckets and nozzle delivery to conditions as to head and power requirement.

THE conning tower of a modern iron-clad warship is only a bombproof pilot-house whence the ship may be steered in time of action, and is not primarily a safe post where there may be kept an outlook upon the enemy. Conning is a very old word for directing the act of steering a ship. It comes from the ancient word "con," to know, to watch, and the conning tower really comes pretty close to a cunning tower, though there may be a certain touch of the whimsical in the idea.

THE unequal thickness of an envelope, caused by the overlapped edges, pasted or unpasted, sometimes affects the beauty and distinctness of addresses printed with a typewriter. An envelope has therefore been devised, cut from a piece of paper of such shape that the folds will not come under the address.

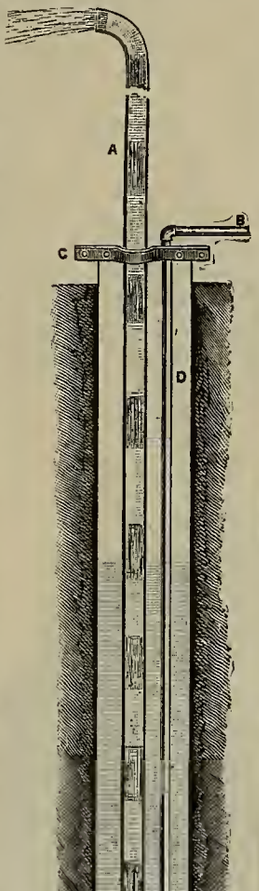
A STEEL CABLE one and one-half inches in diameter, traveling twelve miles an hour, can transmit nearly 2000 horse power.

Pohle Air Lift Pump.

Illustration is given on this page to the Pohle air lift pump, for pumping water by compressed air, made by the Ingersoll-Sergeant Drill Co.

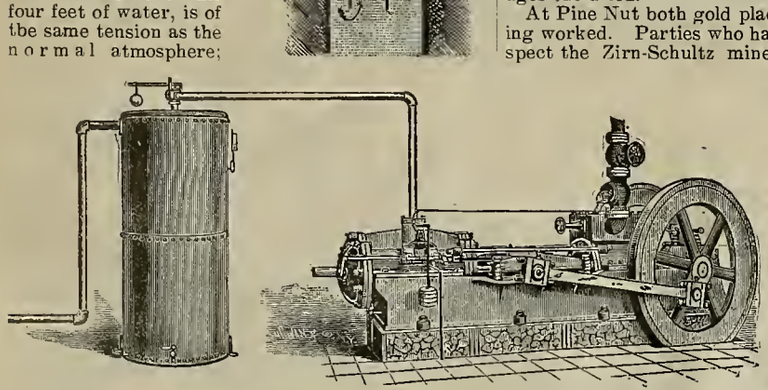
The working principle of this pump is thus explained by the manufacturers:

"In pumping, compressed air is forced through the air pump into the enlarged end at the bottom of the water pipe, thence by the inherent expansive force of the compressed air, layers or pistons of air are formed in the water pipe, which lift and discharge the water layers through the upper end of the water discbarge pipe. At the beginning of the operation, the water surface outside of the pipe and the water surface inside of the pipe are at the same level, hence the vertical pressures per square inch are equal at the submerged end of the pipe, outside and inside. As air is forced into the lower end of the water pipe it forms alternate layers with the water, so that the pressure per square inch of the column thus made up of air and water, as it rises inside of the water pipe, is less than the pressure of water per square inch outside of the pipe. Owing to this difference of pressure, the water flows continually from the outside to witbin the water pipe by gravity force, and its ascent through the pipe is free from shock, jar, or noise of any kind.



"These air sections, or strata of compressed air, form water-tight bodies, which, in their ascent in the act of pumping, permit no 'slipping' or back flow of water. As each air stratum progresses upwards to the spout, it expands on its way in proportion as the overlying weight of water is diminished by its discharge, so that the air section, which may have been, say, 50 lbs. per square inch at first, will be only 1.74 lbs. when it underlies a water layer of four feet in length at the spout, until finally this air section, when it lifts up and throws out this four feet of water, is of the same tension as the normal atmosphere; thus proving that the whole of its energy was used in work, and that this pump is a perfect expansion engine.

"As the weight of the water outside of the discharge pipe (the head) is one-third greater per square inch than the aggregate water sections within the pipe when in operation, it follows that the energy due to this one-third greater weight is utilized in overcoming the resistance of entry into the pipe, and all the friction within it."



THE POHLE AIR LIFT PUMP.

Parke & Lacy Co., 21 and 23 Fremont St., San Francisco, are the coast agents.

The Mines of Nevada.

Written by DAN DE QUILLE.

The mining industry of Nevada is now narrowed down to the working of gold properties—gold-bearing quartz veins and the few placers found here and there in this State. No mines are now being worked for silver alone. It will not pay to mine silver at present anywhere in this State at its price as a commodity; indeed, it is only in exceptional instances that it will pay in any place in the United States or any other country in the world. Here and there bonanzas are found that are so rich that for a time silver can be so cheaply mined that profit can be made at 60 cents an ounce; but count all the work done on the veins of the district, county or State, and it will be found that every ounce of silver obtained has cost from $1.30 to $1.50. It is the same in gold mining. When a man is so fortunate as to hit upon a big deposit of rich ore near the surface he is often able to take out gold at a cost of from three to five dollars an ounce, or even less. But these rich pockets in gold veins and the bonanzas in silver veins are few and far between. They are the great prizes that all who engage in mining hope to secure, but where one man wins thousands lose, and other thousands merely obtain a sufficient amount of the precious metals to keep them alive and digging.

As a small amount of gold is now worth more than a large amount of silver, those of our people still engaged in mining look wholly to the yellow metal for their reward. All gold-bearing veins, both great and small, are being examined and prospected, and the placers are being raked over and worked in the best manner possible, most of them being in regions that are almost or quite waterless.

The most promising gold quartz camp in this part of the State at present is Silver Star district, situated in Esmeralda county. Colonel Ed Bozle, who has just returned from an examination of the mines of that place, is greatly pleased with what he there saw. He tells me it is a region that is full of veins of gold-bearing quartz, and on these he found about twenty mines that will pay. The veins are from four to twelve feet in width, and pay from $20 to $50 a ton. The veins are found to increase in width and richness as depth is attained. Although milling facilities are inadequate large amounts of gold are being taken out and in some of the mines first opened there is in sight ore to the value of several hundred thousand dollars. The mines are equal to the best that have been found in the eastern part of the State, along the Utah west line.

Silver Peak, to the eastward of Silver Star, bids fair to become a rich gold camp. A new thirty-stamp mill is being erected at the peak. W. J. Salkeld, the well-known millwright, has charge of the work. The State Line mill of forty stamps is also to be started up, which will give the Peak mines a total of seventy stamps. The mines are being put in order for Superintendent L. J. Hanchett, a man who has had a vast deal of experience in Pacific Coast mines.

At and about Hawthorne the gold veins are yielding as usual. The arrastras near Hawthorne, which do custom work, are kept in constant operation. They work the ore of the men owning small mines. Much of this ore yields $50 to $100 a ton. It is a good poor man's camp, as rich ore is found at or near the surface. The Lapanta, the oldest mine in the district, is looking better than before in some years. The vein has widened to four feet and averages $20 a ton.

At Pine Nut both gold placers and veins are being worked. Parties who have been allowed to inspect the Zirn-Schultz mine report a "perfect bonanza of large proportions, with many ounces of pure gold in sight." Other veins in the same range are rich in gold.

At most points there is a lack of water for working the placers. Gravel is being hauled to Anderson creek for washing. It pays $5 to the two-horse wagon load. Several men are at this work, and are able to make good wages. Three men and a team take out an average of $100 in four days. The leading mines of the Comstock are holding out well. In Con. Cal. & Virginia they have a new streak on the 1750 level that assays from $33 to $75 a ton. Average from the whole mine is $51.78 a ton. The Crown Point is yielding over 700 tons of ten-dollar gold ore a week. The Chollar ore is paying $24.48 a ton; Seg. Belcher, $26.90; Belcher, $27.19; Silver Hill, $50, and Hale & Norcross, $72.90.

Coast Industrial Notes.

—Nearly 800 men are now employed at the Mare Island navy yard.

—Petaluma will this season increase its shipment of basalt paving blocks.

—The Union Gas Engine Co. will put a gas engine in Chas. L. Fair's new yacht.

—An iron foundry has been established at Flagstaff, Arizona. The first heat was run off last week.

—The Los Angeles fiesta was not a fiasco. It cost $35,000, and the net profit was over $200,000.

—The Valley Road directors have justly rejected the China basin lease as proffered by the Harbor Commissioners—too restrictive.

—According to the Virginia, Nevada, *Enterprise*, at the Bailey sale in Churchill county last week, 100 head of horses went for thirteen cents apiece.

—Messrs. Coons and Nelson have acquired the rights of the Wheeler Electric Line Co., and propose building a road between Aberdeen and Hoquiam, Wash.

—Grant Brothers, who have taken the contract to build the Southern Pacific's new branch line into Pasadena, have begun the work and will push it through to early completion.

—The Northern Pacific will resume the work of arching the Stampede tunnel in the Cascades with brick this summer. A contract for 2,200,000 brick has been awarded to the Union Brick Works of Tacoma.

—Referring to the cheapness of cedar shingles, the Portland *Oregonian* says: "Sawn cedar shingles, the best in the market, are now to be purchased at $1.10 per thousand. A few years ago they sold for $2.75."

—President Wilson Hamilton of the Flagstaff, Durango & San Diego Railroad says his company has the necessary rolling stock and rails to commence work as soon as the survey is completed to Flagstaff, Arizona.

—Ten of the new cars for the Pasadena and Los Angeles electric railway have arrived there. Some of these cars are lettered "Los Angeles and Santa Monica," which indicates the ultimate use to which they are to be put.

—English parties have bought and will consolidate the entire electric street railway system of Portland, Or., with a total mileage of 128 miles. The purchase price is nearly $3,000,000. The original cost was about $2,750,000.

—The Union Iron Works is building a new style concentrator—the Union. They are finishing the new hoisting plant for the Brunswick mine, Nevada City, which will have a capacity to work the mine to a depth of 3000 feet.

—The Fulton Engineering and Shipbuilding Works is building a duplex tandem compound compressor, 220 H. P., driven by a Pelton water wheel, 19 feet diameter, 750-foot head, for the North Star Mining Co., Nevada City, and a compressor for the Golden Cross, San Diego Co., 100 H. P., with Corliss engine, surface condenser.

—The Washburn-Moen Manufacturing Co. of Worcester, Mass., through their coast agent, Frank L. Brown, No. 8 Pine street, have concluded arrangements for the absorption of the California Wire Works. The transfer includes the wire rope and cable plant of the latter company—the manufacturing part of their business.

—Mr. Felts is getting some very good notices of his electric primary battery in the Sacramento papers. The *Record-Union* wants to know, in a leading editorial devoted to Mr. Felts, why it is not possible that a California man has discovered what all electricians so long have sought, and mourned because they found it not. The mantle of Prof. Emme seems to have fallen on Felts.

—The Nevada County Electric Power Company's scheme is practicable and the directors are fast getting the project into tangible shape. The idea, as heretofore explained at length, is to supply power to the mines in Grass Valley and Nevada City districts, it being calculated that electric power can be furnished with the waters of the South Yuba at an annual rate of $75 per H. P.

—The recent high prices of petroleum have stimulated Los Angeles and Ventura oil prospectors, and tend to stimulate the oil trade with Peru, inaugurated by Grace & Co. They already have the Bawnmore running regularly, and have given the Union Iron Works a contract for an oilship, to be built especially for the South American coast petroleum carrying trade. The keel was laid last week.

—The electric power plant now being put in by the South Yuba Water Co. will cost $150,000. A pipe line from Long Valley to Newcastle will generate 1000 H. P. A pole line will be run to Newcastle. The main line will be continued to Rocklin and Sacramento. If the venture prove successful, enough more power can be generated from the company's ditches to equal 2500-horse power, which is sufficient to furnish lights for Sacramento and intermediate points.

—The Sacramento Board of City Trustees finally got together this week and by a vote of seven to two awarded the contract for the A 2 style of pump for the Sacramento city water works to the Edward P. Allis Company for $12,700. The bids for 4000 feet of six-inch water pipe, thirty-one pounds to the foot, were as follows: Baker & Hamilton, 44 cents per foot; Holbrook, Merrill & Stetson, 43.1 cents; Schaw, Ingram & Batcher, 43 cents. The contract was awarded to Schaw, Ingram & Batcher.

—Reports that the Stanford University would be closed at the end of the present term because of lack of funds to pay current expenses are unwarranted. The university has been forced to retrench since the death of Senator Stanford, and the Government suit has tied up a large amount of property on which ready money could be realized, but Mrs. Stanford's personal attorney says that she will never permit the doors to be closed, no matter what sacrifice she may be called upon to make, as even temporary suspension would be wellnigh fatal to the college. The Government suit for $15,000,000 against the Stanford estate, which has prevented distribution, comes up shortly.

—The battleship Oregon is at the Union Iron Works to at last receive the long-delayed armor plates. The latest test of these armor plates was made last week, an eighteen-inch nickel steel Harveyized Carnegie plate, representative of the second lot of 360 tons of side armor for the Oregon being tested with the most satisfactory results. The plate was first fired at with a Holtzer shell from a twelve-inch gun at a velocity of 1465 feet per second. This shell penetrated about five inches and was shattered. The second, or penetration shot, driven by a larger charge of powder at a much higher velocity, penetrated about nine inches, but the manner in which this plate stood the test was regarded by the ordnance officers as showing it to be the best yet tried. To still further test the qualities of the plate, an experimental shot from a thirteen-inch gun was ordered. A Carpenter projectile weighing 1100 pounds was sent at a velocity of 1810 feet per second, with an energy of 24,981 tons. This gun had never before been used in such tests. Although the shot developed a crack, the plate still held together, all the backing and structure behind being crushed. The ability of the plate to keep out other projectiles was shown by the fact that only one armor bolt in the backing was destroyed.

Scientific Progress.

A Difference in Custom.

An American visiting Europe is likely to be struck with the difference between the different European countries and this country in the matter of secrecy in regard to the shop manipulations. It is almost impossible to gain entrance to the large shops there, unless your efforts are seconded by some one of considerable influence, and even then you are rushed through without the chance for examining anything with any degree of closeness. You have all the time the feeling that you are an intruder, and that you are looked upon as having the intention to steal something, not something tangible, but something in the way of items.

While at the Paris exposition, says a writer in the *Tradesman*, I noticed some work in plate iron in which I was very much interested. It was from a large English works. I asked the man in charge of the exhibit as to the probability of being allowed to go through the works. He did not know, but advised that I write the company. I did so and received a reply by return mail granting permission. I had hardly finished reading the letter, which was addressed to the hotel at which I was stopping, when a telegram was handed me, signed by a higher official of the company, to the effect that they would allow no one to go through their works. Afterwards I learned of another American engineer who wrote them for similar permission and received the reply that they would not let him, nor even the President of the United States, see their processes of manufacture.

Soon after coming back to this country a young graduate of the technical school asked me for a letter of introduction to one of the largest and best known machine manufacturing establishments in the country. This I gave him and received a letter from the company thanking me for having done so and saying that they detailed a man who had been with them for many years to show the young man over the works, and at night had persuaded him that he had not seen all their processes he ought to see and had brought him to conclude to remain over and spend the next day in the shops. The contrast coming so quickly magnified the difference.

A day or two after being refused admission to the English shops I met a very intelligent man and incidentally learned from him that he had formerly been in the employ of the same English firm. From him I learned all I wanted to know about the process, as the whole matter on my part was one of curiosity only, except that I should have asked permission to say something in print about the works. I have no doubt that, with the assistance of this man, any good mechanical engineer could have almost literally duplicated the machinery and the operations in the works.

The keeping of trade secrets, especially those of machine shops and foundries, is almost too difficult a thing to be worth trying for; I believe the American practice in the best shops is right. In these shops customers can see for themselves that the processes are good, and future customers are made for the same reason. Let a machine manufacturer guard a secret as closely as he may, if another is determined to get hold of it he will do so, unless the manufacturer does all the work himself.

AUGUSTE STRINDBERG asserts in *Annales Industrielles*, as the result of numerous experiments made by him, that sulphur is a compound of carbon, oxygen and hydrogen, in proportions as yet undetermined. He goes still further than this, and claims that it is not only not a simple body, but not even an original one, being merely a common fossil resin or bitumen. He says that when sulphur is melted at about 120°, it disengages an odor of turpentine or camphor; and if a trace of iodine be added, the odor becomes more marked. If it be heated anew to between 160° and 230°, it loses oxygen and drops to the level of a caoutchouc, of which it assumes the color and consisteney. Then, if the brown and viscous liquid thus obtained be cooled, it preserves its nature for a certain length of time, and then resumes its state of resin.

The Gas Engine and the Steam Engine Joined.

Referring to the discussion of the gas-engine question, a prominent engineer remarked, in conversation, that he failed to see why the gas engine and the steam engine should not be compounded, so to speak. He put the case something in this manner: In the gas engine one of the problems is to keep the cylinder reasonably cool, and in the steam engine to keep the cylinder hot. Now, suppose we have a gas engine running and jacket its cylinder with water, which is then used for boiler-feed water, thus saving the heat which is now thrown away. Then take the exhaust from the gas engine through the jacket of the steam cylinder, and, if necessary, as it probably would be, add a heating chamber for the steam to pass through just before reaching the cylinder, so that more heating surface could be employed. Two such engines adapted to each other would probably mean a relatively small gas engine and a steam engine large enough to carry all the load in case the gas engine refused to work for any reason; and, arranged in this way, each would supplement the other so far as the proper distribution of heat is concerned. The proposition is a novel one, and there is a chance to do some thinking over it. Possibly some one may be so situated as to make it easy to try the plan and let us know the results.—American Machinist.

PROFESSOR CLARKE, of London, prophesies that diamonds of marketable size will soon be manufactured. M. Moissan, of Paris, has manufactured diamonds by melting wrought iron together with carbon, and permitting the mixture to cool very slowly. Under the conditions the carbon became crystallized. Simultaneously Mr. Kroutschoff, of St. Petersburg, got diamond crystals by a similar process, employing silver instead of iron. These artificial diamonds are scarcely big enough to be seen by the naked eye, but they represent the solution of the problem of crystallizing carbon. Dealing with the way diamonds are formed by nature, Prof. Clarke gives the opinion that eruptive matter from deep in the earth bursts out through upper layers of shale, the latter being rich in carbon. Slow cooling follows, and the carbon is crystallized as in the experiments of M. Moissan and Mr. Kroutschoff.

Dividends Wanted.

Many paying properties might pay more, and others just paying expenses might pay dividends, if properly managed.

If in need of a thorough, practical manager, of large experience and well recommended, address

BOX L, MINING AND SCIENTIFIC PRESS.

Tucson, A. T.

Carlisle Gold Mining District.

I have six quartz claims on two parallel leads, 4500x1200, for sale upon reasonable terms. Large ledge: ore goes $10 per ton. Will sell for cash or on a milling proposition. Location, Clifton, Arizona, close to Carlisle District. Send for synoptical report.

J. F. CROSETT,
628 Sacramento St.....San Francisco.

WANTED—A PARTNER

For the manufacture of the

Merralls Hydraulic Quartz Mill,

Simplest, cheapest and best Ore Mill ever invented. Will do more work than stamps. Saves more gold with less power. Wear and tear reduced to a minimum. Call or address M. A. MERRALLS, Room 12, Third Floor, Mills Building, San Francisco, Cal.

Mechanical Progress.

Does Away With the Dead Center.

An engine without "dead centers," and one which will utilize the full force and power of the steam during the whole length of the stroke of the piston, both forward and backward, has been the dream of the inventor for centuries, and that a Salt Lake man has finally accomplished it will be a signal for congratulation, says the Salt Lake *Tribune* of April 29th.

The laurel falls at the feet of James Hayton, a modest little man of some 50 years or more, who gave an exhibition of his machine yesterday afternoon at 2 o'clock in McClure's machine shop, on Green, near Pear street, where the machine was in operation, and invited all to enter. The first and only machine for practical operation that has been built was there, to be seen in full gear and rigging, and while it is a diminutive affair, at the same time it exerts a two-horse power and affords energy enough to operate the machinery of the McClure machine shop, whereas, prior to its advent, an ordinary engine of four-horse power was used.

For six years inventor Hayton has been working upon the principle, and yesterday when the steam was turned on in the presence of the visitors, it was with the consciousness that he had mastered the problem that had baffled so many.

Persons familiar with steam are aware that the ordinary standard engine does its work during a small part of the stroke of the piston—that is, while the crank is at the highest and lowest points of the circle described by it. At the opposite horizontal points of the circle are the dead centers, when the steam is exercising no power and doing no work. The crank, as the machinist will understand, must be carried past these dead centers by the fly wheel, and this is just what the invention whose performances were witnessed by a large number of mining men and machinists yesterday has accomplished.

It successfully does away with the crank, and converts the reciprocal motion of the piston into a circular motion on the driving shaft, revolving continuously with all the force of the crank until at full lever.

The engine, while exercising but two-horse power, with thirty pounds of steam pressure, runs the lathes, drill, planers and other machines contained in the establishment.

The inventor claims that his engine may be constructed in any size, from a one-horse power to 5000-horse power, and that it will ultimately set aside the old standard engine now in use.

The visitors were very much pleased with the exhibition.

SHAFTING is very greatly handicapped by the faulty application of the pulleys and belts. The most serious error made in this connection is that of running unreasonably tight belts. It is amazing how much power is wasted in this way, to say nothing of the trouble of broken pulleys, hot boxes, etc. The enormous and absolutely useless pressure thus put upon the pulleys must in time break them, besides wearing out the system of shafting and bearings. If manufacturers realized what these ridiculously tight belts cost them in a year, they would give vent to some very strong and expressive language. It has been calculated by several eminent engineers that the loss of power, from friction alone, in some of the best equipped mills in the country, is from 22% to as high as 39%. It is unreasonable to suppose that the minimum friction would consume this amount of power, and no other cause is so potent in increasing friction as undue tightness of belts, which, when they number by hundreds in a mill, easily account for the great loss of power referred to.

SAYS a writer on mechanics: A man in charge of a small boiler has had a conflict with one of his numerous bosses. The boiler leaked at one of the fittings and the fireman saved the water and would use it over again. The boss observed this and ordered him to quit it, and finally went to the owner and complained, saying that the fireman was using water that had been through the boiler and "had all the steam taken out of it." This is another idea of how steam is obtained.

The Pelton System of Power

Represents the highest development yet attained in water wheel practice and affords the most simple, efficient and economical means of utilizing water for power purposes.

Six Thousand Wheels Now Running,

Aggregating over 400,000 horse power. Adaptation made to all conditions and every variety of service.

Electric Power Transmission.

PELTON WHEELS are the recognized standard for electrical work and are running a majority of the stations of this character in all parts of the world.

Catalogues furnished upon application. Address

Electrical Progress.

THE *Moniteur Industriel* states that Capt. Exler, of the Austrian army, has found that a 16 C. P. incandescent lamp gives off a maximum temperature of 94° C., and a lamp of 25 C. P. 101° C. Two lamps placed in a woodeu receptacle yielded a temperature of 215° C., decomposing explosives such as gunpowder, ecrasite, pyroxyline, etc., but without exploding them. The receptacle having been filled with water, the latter became in a state of ebullition at the end of fifteen minutes. In case of the breakage of the lamps, the powder and pyroxyline do not ignite, but this is not the case if an explosive gaseous mixture is present. The captain points out that too many precautions cannot be taken, notwithstanding the use of electric lamps, which, while reducing the danger of an explosion, do not completely remove that danger. From the experiments made, it is held that the solution of the problem does not in any way lie in the employment of a double bulb with an intermediate closed space filled with air or water. The heating of the water would be avoided by the use of a reservoir having doublc communicatiou with the external euvelope, an arraugemcnt by which would be established a continuous current, and which would allow of the cooling of the water. But in order that the latter may be sufficient, the volume of water necessary would render the arrangement heavy and cumbersome, and the method is cousequently not practical. A ratioual solution for the lighting of places where gas or explosive materials are present seems to be, according to the captain, simply in arranging the incandescent lamp in a glass cylinder closed at both ends by means of metallic cloth; the current of air would freshen the bulb, and the slight heating of the air passing out would not be detrimental. In case of the breakage of the bulb, the combustion of the filament would produce at most only a small internal explosion, as in miners' lamps, incapable of transmitting fire outside.

THE electric candle is in great request in England for the lighting and decoration of dining and other tables. Au iugenious device for lighting the candles is provided by placing small pads under the table cloth, aud taking the current from them by means of two pin points in the base of the candlestick. The candles, of course, are extinguished on being taken from the table, and are relighted when they are replaced in the proper position. They are so arranged that the bulb and the glass imitation of a wax candle can be removed, when the caudlestick can be used for an ordiuary candle. Wheu used with shades of colored silk the electric candle makes one of the prettiest additions to a dinner table that it is possible to imagine.

THE trustees of the Los Angeles Consolidated Electric Railway Company, in compliance with a demand from the boudholders, will declare all of the $3,000,000 issue of bonds of the company now due and payable, but, as the company will not be able to pay them, the road will be sold by auction to the highest bidder to satisfy the bondholders. This will be the last step prior to the assumption of the ownership of the road by the Los Angeles Railway Compauy, the corporation formed by the majority of the bondholders last March to protect their interests and securc control of the road.

THE very hard steel used for the cyliuder wheel of ordinary watches is very apt to become highly magnetized when brought near dynamos running; and this magnetization, combined with the earth's magnetism, always causes the watch to get slow, and often to stop altogether. In order to annihilate this magnetization, a natural magnet or a powerful electro-magnet should be placed in a horizontal position—ou a table, for instance—and the watch held horizontally about half a yard off ou a level with the magnet. The watch must then be brought slowly nearer the magnet, while being turned slowly, and, at the same time, as regularly as possible, between the fingers, as on a vertical axis. When the poles of the maguets are reached, the turuing of the watch is to be continued, while being gradually withdrawn until the starting point is reached.

A NEW MATERIAL for conducting sound has been utilized by a Pittsburg firm, which advertises a telephone fitted with a receiver capable of transmitting speech perfectly with the operator eight or ten feet away from the 'phone. The diaphragm is made of aluminum and is exceedingly sensitive. This arrangement will enable operators to use the instrument without leaving their desks and will be a stride in advance of the present method.—Inventive age.

AFTER five years' work A. P. Crell, of Ionia, Mich., has invented an electric mail car which, he claims, will make the journey from New York to Chicago in five hours, or at the rate of 200 miles an hour. The car is made of steel and weighs forty tous. It is to run over an elevated track of steel throughout, eighteen feet from the ground aud supported by a cable. It souuds very impracticable.

A HOLLANDER has invented a process of sterilizing milk by subjecting it to the passage of an alternatiug electric current. All micro-organisms taken up by the milk from the air, etc., are permanently destroyed by the electric current. This germ-killiug quality of the electric current does not hurt the milk.

J. M. BLEYER, in an article iu the *Electrical Review*, argues that the true cause of death by electrification, as carried out by the prescribed laws of the State of New York, is due to "dynamic apoplexy"—another case of "heart failure."

THE first electrically driveu quartz battery in Australia was recently started to work at Hillgrove, New South Wales. The source of energy is six miles away, and the installation achieved a complete success.

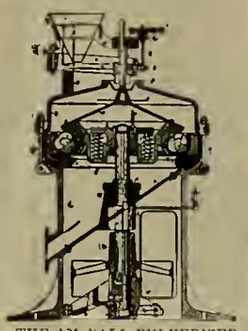
First Prize and Gold Medal Awarded by World's Fair, 1893.

Office of THE CLEVELAND IRON ORE PAINT CO. and THE GARRY IRON ROOFING CO., CLEVELAND, O. Jan. 25, 1894.

The American Mining & Milling Machinery Co., Cleveland, O.:

GENTLEMEN:—We purchased a No. 2 American Rock Breaker and a No. 2 American Ball Pulverizer from your company about one year ago. The latter part of April, 1893, we started up for regular work, since which time we have run both of said machines to the full extent of our demands and to our entire satisfaction. The first 700 tons of hard iron ore that we pulverized for paint purposes was ground without taking the Pulverizer apart, and without expending one dollar for repairs for either of these machines. Of the 900 tons spoken of, about 200 tons was Lake Superior Specular iron ore, containing some 70 per cent iron; a very difficult ore to pulverize. The remainder was a red fossiliferous iron ore, carrying quite a per cent of silex, which cuts out buhr-stones rapidly. We find that the steel balls, which were when new 5 in. in diameter, now caliper 4⅝ in., and are perfectly round and smooth. The grinding track shows very little wear, and the driving track shows LESS; in fact, the wear is almost imperceptible. These two machines crush and pulverize more than one ton per hour with LESS than 12 H. P. We do not know of any Crusher or Pulverizer that can compare with the output of these two machines in quantity, quality, small amount of wear and tear, and like power. In our opinion, you cannot recommend them too highly. Very truly yours,

CLEVELAND IRON ORE PAINT CO.



THE AM. BALL PULVERIZER. Morris Patent.

—FOR SALE BY—

The Eureka Company,

OF SAN FRANCISCO.

ROOM 1. - 426 CALIFORNIA STREET, SAN FRANCISCO.

The Russell Process.

For information concerning this process for the reduction of ores containing precious metals, and terms of license, apply to

THE RUSSELL PROCESS CO.,

Park City, Utah.

RISDON IRON WORKS.

Office and Works: Cor. Beale and Howard Sts., San Francisco.

Cable Address: "RISDON'S" San Francisco.

MANUFACTURERS OF

Johnston's Concentrator, Bryan Mills,

Challenge Ore Feeders, Air Compressors,

MINING, MILLING, PUMPING and HOISTING PLANTS.

UNION IRON WORKS,

CORNER FIRST AND MISSION STREETS, - - - - SAN FRANCISCO, CAL.

—MANUFACTURERS OF—

MINING AND MILLING MACHINERY,

Automatic Cut-Off Engines, High-Speed Engines, Hoisting Engines, Quartz Mills, Manty Chili Mills, Rolls and Concentrating Machinery, Dodd Sigmoidal Water Wheel, PUMPS--Cornish and Other, Copper and Lead Furnaces, All Classes of Marine Work.

SHIP BUILDERS. ★ BUILDERS OF U. S. WAR SHIPS. ★ HYDRAULIC LIFT DOCK.

NEW YORK OFFICE: 145 BROADWAY. CABLE ADDRESS: "UNION."

Attention Miners!

W. W. MONTAGUE & CO.

—ARE MANUFACTURERS OF—

Riveted Iron and Steel

Water Pipe

For Hydraulic Mining, Mills and Power Plants.

IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.

309 to 317 Market Street, San Francisco.

FRANCIS SMITH & CO.,

—MANUFACTURERS OF—

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

130 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Mining Pipe!

STEEL OR IRON.—We make pipe of either, but recommend STEEL, it being superior to iron in many particulars and inferior in none.

COATING.—We use great care in COATING our pipe with a HOT solution of Double Refined Asphaltum and Maltha.

COMPETITORS.—Our competitors say we have the best appointed Pipe Shop on the Coast.

SCHAW, INGRAM, BATCHER & CO., Hardware Merchants,

SACRAMENTO, CAL.

DEWEY & CO., 220 Market St., SAN FRANCISCO,

PATENT SOLICITORS.

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY & CO., Patent Agents, 220 Market St., S.F.**

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

GENERAL NOTES.—*Republican:* At the Zeila the entire works—miue, mill, chlorination works—are in full operation, giving employment to 100 men.

At the South Eureka a coutract is let to run 1200 feet of drift at the 1000-foot level, at $3.48 per foot.

MISCELLANEOUS.—F. A. Serine and R. K. McCoy have been operating the Anaconda quartz mine near Pine Grove for several months past. The claim appears to be of a pockety nature. A small crushing was made at the Levezzo mill, of surface rock, but it failed to pay expenses. This crushing was made merely to test the general character of the quartz. There is a streak of red clay met with in the claim resembling putty in its nature. A small ball of this was used as a candlestick. A few days ago one of the owners was working with his hands and felt something hard. Taking out the substance, he found it to be a nugget of gold worth between $4 and $5.

THE MECHANICS MINE.—The Mechanics mine will soon be opeued under the foremanship of George Taylor. T. D. Valentine of San Francisco has a hond on the property from Peter Fagan, the owner. It is located near Sutter Creek.

SOUTH EUREKA.—The South Eureka contractors are runuing the main drift from the 1050 level toward the rich body of ore which was encountered on the 900 level, a distance of 800 feet southeasterly from the main incline. It will take three months to tap the ledge.

Butte.

GENERAL NOTES.—*Times:* The Wright-Durgan miue on the Dogtown ridge is now running by the drift process and giving employment to fifteen men.

The old Ed Davis drift mino ou Dry creek is in operation and employs eight men.

Light & Mumford are ruuning their drift mine on Dry creek and employ four men.

Two loads of sulphuretted ore were sent down last week from the Gold Bank miue at Forbestown for shipment to San Fraucisco.

The Bellingsley hydraulic mine on Mountain House creek is ruuning steadily and giving work to six men.

Berry & Co.'s hydraulic mine on Mountain House creek now employs eight men and is paying well.

Grant's mine on Busb creek employs eight to ten men and pays well.

The Spring Valley quartz mine, near Oregon City, will resume operations in a short time. A San Francisco company has charge of it. Will Wilson is the superintendent.

The Matti mine, Green & Elliott proprietors, will resume operations next month.

The McNair mine, Frederick Bros. proprietors, will begin operations soon. This was always cousidered a rich mine, and now a tunnel will be run in 350 feet and probably a large force of men will be given work.

The mine ou the Hipps place will soon erect a five-stamp mill.

The Four Hills quartz mine, near Quincy, will resume operations soon.

At the Summit, or Perkins mine, the ten-stamp mill has heen run constantly all winter. The snow is now fifteen feet deep.

Calaveras.

THE ANGELS MINE.—*Echo:* The Angels mine, a few hundred yards north of the celebrated Utica mine, will be started up the 1st of June. It is owned by Coleman. Tarpey & Co. Electrical power will he used to run all the machinery at the mine.

THE LEONARD MINE.—A force of men have been put to work on the Leonard mine. The force is working in the tunnel and crosscutting to a new ledge on the east. Supt. Weymouth is very hopeful of striking a rich lead a little further eastward, as all indications point to such strike.

THE WOOD MINE.—The Wood mine at Robinson's Ferry has been bonded by a company who are pumping the water out preparatory to developing the property.

El Dorado.

GENERAL NOTES.—*Democrat:* The Avansino gravel mine at Pleasant valley has been closed down, and the machinery used in sinking removed. The channel was reached at a depth of 100 feet, but the gravel found would not justify further development, hence the suspension.

Operations at the Lone Star mine, above Smith's Flat, have beeu temporarily suspended, pending the construction of a cylindrical revolving crusher, which is to take the place of the arrastra formerly used.

The Transcendent mine, one mile west of the Taylor, is a new mine. The ore is impregnated with sulphurets, but prospects well in fine gold. It is thought to be good for at least $10 per ton in free gold. They have out about 200 tons of ore, and will soon make a mill test at the Defiance mill.

Work is being done on the Collins mine, with good prospects.

The Emma mine is being worked as usual, and some good pockets are being taken out.

Humboldt.

ORLEANS BAR.—*Eel River Advance:* Maurice Vivier returned to Fortuna from Orleans Bar, where he had been prospecting for two or three weeks, and he brought back glowing accounts of that mining section. It is his opinion that $2.50 to $3 a day per man can be made in those "diggin's," and it is his intention to return to that place to further investigate mining possibilities, with the view of enlisting capital to take hold in that section which in times past has been one of the richest placer mining districts in the State, and with improved mining apparatus it would yet yield a large amount of gold.

Kern.

LOWER GOLER.—James and Stevens have made an average of $50 per day and Kuffle and Swartout an average of $15 a day for the past week taking gold dust out of their claims.

The Benson brothers are putting a plaut on their mining claim, and it will be in operation in a few days. They have taken out of the ground over $40,000 in the past two years. Mr. Ellison is doing equally as well.

There are several good quartz miues reported in Jawbone canyon about twenty-five miles from the Sixteen-mile house. A ten-stamp mill is being put in on one of the claims.

AMALIE DISTRICT.

Since the discovery of the new ledge in the Amalie miue, reported in the last issue, every available bit of ground in the district has been located.

Nevada.

THE NATIONAL MINE.—*Union:* The National mine at Grauiteville has been pumped clear of water and operatious will be resumed next week.

THE NORAMBAGUA.—*Tidings:* The Norambagua mine is opeued up and the several parties who are workiug it will have their ore crushed at the Perrin mill. Some of the ore has already been crushed hut the roads have been so soft that hauliug has been postponed. About one hundred loads of ore will be put through the mill and it is expected that the work of crushiug will be resumed next week.

THE ROSE HILL.—*Tidings:* The Rose Hill machinery is now ready for operation. The engine is a six-horse power gasoline machine, and cost, laid down in Grass Valley, $635. The stamps are three in number, weigh 850 pounds, and at average speed will drop eighty times per minute. This three-stamp battery cost, material and all, $815. This price includes a self-feeder. It is expected that twelve tons of ore can be crushed each twenty-four hours. It required less than a week to set up the engine and put the stamps in position after the arrival of the machinery, though some preliminary work has been done in framing timbers. The building to contain the machinery cost $800, making the total cost of the entire plant about $2250. The engine will consume 1¼ gallons of gasoline per hour, the cost of which is twelve cents per gallon when purchased in bulk. Thus the cost for power will be from eighteen to twenty cents per hour or between $4 and $5 per day.

The mine at present has no concentrator for saving sulphurets, the ore being mainly free gold ore. If, however, it be found necessary, a concentrator can be added.

J. M. Wishart, the superintendent, with his force of fifteen or twenty men, is taking out ore.

WASHINGTON DISTRICT.—*Herald:* An increased force of men has been put on at the Spanish miue preparatory to putting up the new mill. Fred Bradley is overseeing the work.

Henry Phillips, superintendent of the Mountain View and other adjoining mines, came up Friday from San Francisco on his way to the mine. He brought up a quantity of supplies for the mine, among them a Joues' patent rock drill which he will immediately set up. Some San Francisco parties accompanied Mr. Phillips, who will inspect several of the ledges in this vicinity and make tests of the ore.

Messrs. Boulanger and Haskell, of San Francisco, are in town inspecting the St. Patrick mine.

Messrs. Hall, Geiser, Miller and Rourke are here to examine the Arctic and other property in the vicinity of Canyon creek.

The mill at Blue Jay mine is runniug. The owners have some fine rock on the dump, which they are putting through.

Thirty stamps are kept constantly dropping at the Oak Tree mine, and a full force of men are at work taking out ore.

GOLD BAR AND GOLD POINT.—*Transcript:* A steam plant is being put up at the Gold Bar mine. Good prospects are reported and drifting will be commenced soon.

The ten-stamp mill at the Gold Point mine began crushing again Monday. Rock enough to keep it running some time is now on the dump.

Placer.

THE MARGUERITE.—The Marguerite mine has not shut down. The men who had the contract to sink the sbaft a certain number of feet have given it up and a new contract has been let to other parties.

THE BOULDER MINE.—*Republican:* The employees of the Boulder mine, of Ophir, which closed dowu last week, were informed by Superintendent Brown that they would be paid off last Saturday. Saturday came, and with it the meu for their pay, but alas, it never materialized. It was later ascertained, so we are informed, that the money for the bullion, which had been shipped to the mint at San Francisco, was expected to arrive at Ophir Saturday morning but it had been headed off at Sacramento by the Superintendent. The men are very anxious of his whereabouts which is at present unknowu. The loss of the money is a great blow to the little mining town of Ophir, as the stores there had giveu the men time on their purchases knowing that the money was due them. The miners, about twenty in number, have lost on an average, $100 each, but, undaunted by this severe loss, they have taken the mine themselves and propose to work it until every dollar is paid up. The ore is very good in the mine and they will probably not lose in the end.

A RICH STRIKE.—*Argus:* A rich strike was made at the Marguerite, near town, Tuesday morning. They are down over 300 feet and have had fine prospects all along, but on Tuesday they struck a five-foot ledge of some of the prettiest ore we have seen. It will go $60 to the ton.

San Diego.

JULIAN DISTRICT.—The Ready Relief Miuing Company has let a contract for sinking a 100-foot shaft on the Redman mine. It is theu intended to run a drift under the creek, connecting with the Ready Relief mine. The pump and hoisting machinery in the Redman is in place and in working operation, being run by water power from the Ready Relief plant.

IN THE CHOCOLATE MOUNTAINS.—Two gold mines have been sold in the extreme eastern part of the county in the Chocolate Mountain range by L. E. Auhury of San Diego to Kansas City men, who are credited with an intention to pump water from the Colorado river and build a five-stamp mill.

Sierra.

FROM SIERRA CITY.—At the Bonanza mine, over forty men have been thrown out of employmont, owing to the stopping of that mine, owing to temporary disagreement among the owners.

After a run of twenty-eight days, the Butte Saddle made a clean-up of $6000. The company have a ten-stamp mill, but for several days past they have only run five stamps.

The Sierra Buttes pays a monthly dividend to its owners. A few days ago they discovered another rich ledge in the mine.

Trinity.

RICH RETURNS.—The mines of Trinity county are yielding rich returns this year. Many new quartz mines are being opened, and the yield of gold from that county bids fair to exceed the largest amouut taken from that county in receut years.

Ellery Bros.—Elias and James—have a bonanza in quartz near French Gulch, according to reports. They have already cleaned up a small fortune from only two runs.

A French Gulch syndicate are the reported purchasers of the Jack Strode mine at Trinity Center. This mine shows a fine lot of ore chutes, milling from $50 to $100 per ton.

Tuolumne.

GENERAL NOTES.—The Mammoth miue is being vigorously opened by Wm. Johns. Two tunnels are being run with excellent prospects. The lowest will connect with the mill, which will be built as soon as lumber can be secured for its erection. Forty stamps will be set, to be supplemental, as soon as the mine's development warrants an increase to sixty stamps.

Rich ore is being taken from the Jumper mine, from both levels north and south. The mill is ruuning day aud night. The ore is improving as developments proceed. The ore body is very extensive, needing a larger mill.

The Golden Rule mine, north of the Jumper, is in the same black metallic slate formation. It is being developed, and its former record is now verified by the present rich finds.

The Miller & Holmes Consolidated Co. comprises the Gray Eagle, Nyman and Knox & Boyle, all situated south of the App mine, Quartz mountain. Work is being vigorously carried on in these shafts simultaneously. Ore of a good quality is being extracted. This company is putting in an electric plant, power derived from Wood's creek.

NEVADA.

ESMERALDA CO.

A BIG STORY.—J. A. Yerington who has a bond on the Hard Scrabble mine in Silver Star district gives the Salt Lake *Tribune* a big statement about it. He says 6000 tons are now in sight, and the ore is supposed to run from $90 to $100 per ton in gold, and after it had been opened up to a depth of 165 feet and a ten-foot vein had been developed, assays were obtained from the full face giving a value of $163 in gold.

The district lies at an altitude of 7000 feet, and until August, 1892, was unknown as a gold camp. Prior to that time, it had been a moderate silver district, but the demonetization of that metal rendered the mine worthless, and the camp was abandoned. It was on the edge of a mule trail that the first signs of gold ore were discovered, and on this discovery the Hard Scrabble location was made.

"The ore has paid from the grass roots down and in the first surface workings, 118 tons of ore milled out over $10,000 in a crude stamp mill that had been hastily constructed.

"Many experts have visited the district, among others Professor Potter of St. Louis and Governor Colcord, and the unanimous opinion is that the mother lode has been discovered between the Excelsoir and Santa Fe ranges of the Sierra Nevadas. The vein appears to be continuous, and the only interruption yet found are lateral seams of oxidized silver ores."

PROSPECTING ACTIVE.—Prospecting is very active in the several gold camps of Esmeralda county. New finds continue to be reported at Silver Star, and some of these are very rich. For a while it was thought that the first locators had got all the rich veins, but a recent find shows that in mining, as in all else, there are "as good fish in the sea as ever have been caught." In the West it was said of rattlesnakes, "When there is one always look for two," and it is about the same as regards mineral veins. Where one big, rich gold vein has been found other good veins are pretty sure to exist. A good indication of the value of the several Esmeralda gold camps is that one finds nobody coming back from any one of them. It is better to live fat on a four-inch gold vein than to go hungry on a forty-foot silver lode.

HUMBOLDT CO.

THE KENNEDY GOLD MINES.—*Journal:* Kennedy has merit and will prove its worth, though laboriug under great disadvantages. The mines were discovered by poor men when the mining business was at low ebb in Nevada. The discoverers shipped a few tons of selected ore to the Reno Reduction Works from which they realized a few thousand dollars, which they expended in developments. A year ago some of the most promising mines in the district were bonded to an adventurer. A quartz mill built in Chicago many years ago was removed from another district to Kennedy. The process of amalgamation, which was the simplest known, was not adapted to the ores of Kennedy; the adventurer left, leaving only his creditors to regret his departure, and the rich district was given what in mining parlance is termed a "black eye." The mine owners, all of whom, as is usually the case in new districts, are poor men who are working energetically to develop their properties, but without money or credit they find it up-hill business. Ores are being selected from the richest of the mines for shipment to the Selby Smelting Works in California. This involves an average outlay of about $30 per ton. It is seldom, even in the best paying gold miues, that ores can be found in quantity that will average that amount, hence Kennedy cannot be prosperous until works are erected on the ground that will treat the ores successfully. The general opinion of mining men is that there is abundance of gold-bearing ores in the district, and that all is required to make it one of the most productive aud prosperous in the country is bome works for the reduction of the ores, at a cost of $15 to $20 per ton. That such works will be erected in the near future cannot be doubted, and when they are Kennedy will be a lively camp.

NYE CO.

AROUND GRANTSVILLE. — Thos. Mitchell, agent for F. C. Nichols of Bridgeport, Conn., has sold the Ellsworth ten-stamp quartz mill to Theo. Cirac of Grantsville, who will move it to Union Canyon to work his gold ore from the North Belle mine.

T. J. Bell, in his placer mines back of lone, is turning out $100 every four days.

ARIZONA.

SILVER BELL.—There are sixty men working on the Silver Bell under Superintendent R. Hamilton, who also has charge of the smelter at Tucson.

REPORTED RICH.—*Journal-Miner:* There is considerable excitement over recent strikes in the mountains between Thumb Butto and Copper Basin, and a dozen or more locations have already been made in that vicinity. The ore near the surface is fabulously rich in gold. The new finds are located within six to eight miles of Prescott.

COLORADO.

AT FLORENCE.—*Record:* The cyanide plant at Florence has commenced operations. The full capacity is 100 tons per day.

INCORPORATED AT VICTOR.—The Fairview Gold Mining and Milling Company is incorporated with a capital stock of $1,000,000, to operate at Victor. The incorporators are S. B. Smith, J. H. Purnell, P. W. Harrington, J. Hastings and A. V. Purnell.

LEADVILLE.

TWO SILVER STRIKES.—While the gold properties have been attracting so much attention during the past few months, the silver properties have not been idle, and in addition to the regular shipments of iron and silver ore, much important development work has been carried on which is now resulting in some very excellent new discoveries. The latlest strike is that made by the Northern Mining company in the Capital shaft. This shaft was worked for a long time by the Carleton Brothers and a few months ago they found it necessary on account of the depth they had to go, and also the large amount of water they had to handle, to form a mining company. This was done and was known as the Northern, and in which some of the leading mining men of the camp are interested. Much important work has been done since that time, and some good ore encountered, but the biggest strike was made yesterday. In one of the drifts run out a body of chlorides of the richest kiud has been eucountered. The assays from this ore are something immense. The general average of the ore that is uncovered is about 800 ounces in silver to the ton, while some of it runs away up into the thousands. Of course, at present it is impossible to say the extent of this strike, but the management believe they have a good ore body. At any rate the chlorides that they cut into are the finest seen in the camp for many a day.

Another important silver property that has forged to the front is the Bohn shaft. The streak of ore which Major Bohn was following has gradually opened out and bas run into an ore body. The actual extent of the chute is not known, but so far as is proved up it is at least fifty feet wide. The breast is very valuable, as assays show the lowest grade has not less than fifty ounces in siver, while some of the first-class shipping ore runs as high as 700 ounces. The shaft is already on a paying basis and promises to develop into something very rich.

HINSDALE CO.

THE GOLDEN FLEECE.—Lake City *Phonograph:* The output of the Golden Fleece last month amounted to over $39,000. The company is working a force of about seventy-five men, but only twenty-five men are employed in taking out ore for shipment, the rest being engaged in development work. The regular two per cent. dividend was paid by the company last Monday, which amounted to $12,000.

IDAHO.

AT SILVER CITY.—The Black Jack is running along as usual, milling about twenty-three tous of ore daily. Sixty-five men are employed. The Idaho tunnel is in 2000 feet. Between 100 and 150 feet is yet to drive before striking the ledge. Eight shifts with power drills are working in the solid granite, but good headway is being made.

A WALLACE dispatch of the 7th says: Operations at the Hunter mine at Mullen were abruptly terminated last night. Yesterday President Henry of the Miners' Union went

to Mullon and advised Martin Curran, the superintendent, that if he did not raise the wages to the Canyon Creek scale or quit work the Union of Canyon Creek would be over there several hundred strong, and they would run him out of the country and possibly kill him, and that the mill would probably be blown to pieces. Superintendent Curran wired to Dennis Ryan, one of the principal owners, living at St. Paul, as follows:

"Compelled to quit or take chances of having the mill blown up and myself run out of the country. Answer."

The reply came to close up the mine and mill. Consequently, the men were discharged last night and paid off this morning. The mine has been in operation only a week.

THE BUNKER HILL AND SULLIVAN.—A Wardner dispatch of the 8th says: The Bunker Hill and Sullivan management, having expressed a willingness to resume work in their mine at $3 for miners and $2.50 for shovellers, the business men of Wardoer and Kellogg drew up this petition, which is being generally signed:

"We, the undersigned, citizens of Wardner and Kellogg, in consideration of the extremely low price of lead and silver, and in further consideration of the fact that the cost of living has decreased, believe that while these low prices continue $3 per day for miners and $2.50 for day laborers are fair and just rates of wages.

"We further believe that the Bunker Hill and Sullivan Mining and Concentrating Company has the same right to manage their own affairs as we have to manage ours. We hereby pledge the company our cordial support in its determination to pay no higher wages while prices of lead and silver are so low, it being understood that the said company will restore wages to the former basis of $3.50 and $3 whenever the prices of lead and silver advance so that the combined value in New York of 100 pounds of lead to 2½ ounces of silver shall amount to $6."

It is believed the mine will resume on this basis. About 400 men are employed.

NEW MEXICO.

RESUMED OPERATIONS.—The New Mexico and Arizona Smelting Company's smelter at Ivanhoe is working. While it was undergoing repairs the company operated its properties. Hundreds of tons of ore are now on the ground ready for treatment. The smelter has been relined and is reported in better condition than before the shut-down.

A MINING DEAL.—An Albuquerque dispatch reports that the sale of a one-fourth interest in the Crown Point mine, one of the best properties in the Cochiti mining district, was consummated this week, $10,000 being the price paid. The Crown Point is a paying mine, and several carloads of ore shipped to the smelters carry over $200 in gold to the ton.

OREGON.

BAKER CO.

A PROSPEROUS REGION.—There are few idle men around Baker City. All along the line, from Baker into Sumpter valley, there are evidences of prosperity in the various mining fields. Every little creek seems to be a stream of mud, instead of water. They have discharged all the Chinese, and Americans are taking charge of the placer fields that Celestials formerly had exclusive possession of. The appreciation of gold is warranting miners in venturing on little veins which do not exceed from four to six inches in thickness.

The Pix mine, lately sold for $35,000 cash to a New York company, is employing a large crew of men. They are working the mine by shaft and the vein is small. It does not exceed ten inches, yet it is rich in gold.

The Bonanza has lately become the chief rival of the Virtue. With ten stamps running full blast, it has taken out $26,000. It is in a mineral zone, with no walls, or any evidence of such. The vein is from four to six feet thick, and is averaging about $50 to the ton. Mr. Geiser, the manager, is now sinking a double shaft, 480 feet in depth, that will be four feet wide in the clear by eight feet wide.

The Cable mine, formerly known as the La Belle, has been employing a large crew of men the entire winter.

The Phœnix, lately purchased by the same New York company that purchased the Pix, is also a gold producer. There is little being accomplished in placers, for there is less snow than for more than thirty years, and it is only gradually melting away, the soil absorbing the moisture completely before it reaches the ditches.

JACKSON CO.

THE QUINE MINE.—The placer mining and milling plant which will work the Quine mine at Riddle consists of two boilers of 35-horse power and a pump with a 12-inch suction and a 10-inch discharge, with a capacity of 2000 gallons per minute.

GOLDEN STANDARD.—H. D. Kuhli writes from Gall's Creek district that a richer body of ore than ever has been struck in the Golden Standard mine. He says that as high as $2 has been obtained from a handful of it, and enthusiastically adds that he is now asking $50,000 for the mine.

WASHINGTON.

THE CONCONULLY COUNTRY.—The Bridgeport Mining & Milling Company intend to resume development operations on their Mineral Hill property. Last season they spent $20,000. They have a fifty-horse power boiler, a forty-horse power or five-drill capacity air compressor, a hoisting engine and pump—the latter with a capacity of 3000 gallons per hour—two drills, and a sawmill of 5000 feet per day capacity. Where the plant is located, and which point it is proposed to make the base of operations in the development of the entire group of mines, there is now a 100-foot shaft which is to be sunk 200 feet deeper, and they will run drifts and crosscuts to open up the different leads and ore bodies. There is a body of ore where the shaft is being sunk and another about 500 feet farther north, as well as several parallel veins which it is proposed to prospect and develop from the 300-foot level of the present workings. The ore averages about sixty ounces in silver and $10 in gold per ton, and carries 15% lead. The company is composed of New England people, mostly from Bridgeport, Connecticut.

CANADA.

RAINY LAKE ATTRACTING ATTENTION.—"A gold fever unprecedented in Canadian history" is reported in what is known as the Rainy Lake region of Ontario, in the wild and almost inaccessible territory that is best reached either from Port Arthur or from the mining lands on the Minnesota side of the lake. There is now probably 2500 men in a small district, where, with the exception of Indians, not a man was to be found a year ago. A dispatch from Quebec says: "The miners are pushing in rapidly, coming from all parts of the world."

BRITISH COLUMBIA.

A GENERAL STATEMENT.—Miners are scattered all over the interior of British Columbia, and the gravel along the rivers and streams in the province is being raked by a roving army of several hundred men.

There is some stir at Rossland, the latest boom town of British Columbia. Harry Baldwin made a discovery of gold quartz a few miles from Rossland which assayed $22 to the ton and the whole town went wild. There was a stampede in the direction of the find. All came back disappointed, for no other discoveries of any great importance in that section have been made.

The Trail Creek country is said to be a good place to keep away from. The country is overrun and expenses are heavy.

GENERAL MINING NEWS.—About 150 men are working the placers on Carihoo creek.

One monitor is working on Forty-Nine creek, near Nelson.

Up to April 17th, 2,337 tons of ore went through Nakusp from Slocan.

With silver at 60 cents it is estimated that the Slocan Star shows $2,000,000 worth of ore.

Col. Peyton, of the Le Roi Mining Company, has booded the Wagner group, Lardo, for $15,000.

The Hall Mines Company is figuring on the cost of a smelter at Nelson; seventy men are working at the mine.

The Mollie Hughes is the last Slocan shipping mine. A small quantity was sent to the Pilot Bay smelter.

The Robert E. Lee and Maid of Erin, at the Forks of Trail creek, show a vein of ore 15 feet thick, running $10 to $16 to the ton.

The Revelstoke smelter property has been purchased by a Chicago firm.

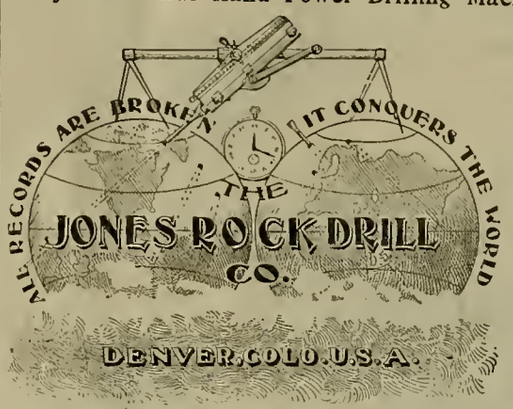
Messrs. Carter & Clarke have had refunded them $934 10, duty paid on a concentrating plant a year ago.

The Noble Five, Slocan, has remained in the hands of the original locators. They have shipped 1,050 tons of ore, which paid every dollar expended on the mine.

News comes of prospecting and assessment work going on in Boundary creek and Midway districts. The shaft on the Last Chance is to be deepened. The four foot vein widens the deeper it is followed.

James Breen, representing smelter companies of Butte, Mont., has been in Nelson. He says that if Nelson can show that ore can be smelted there cheaper than on the American side, the smelter will go up there without any bonus.

THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

Oil Fuel for Locomotives.

President G. B. Leighton, of the Los Angeles Termiual Railway, states that a Baldwin eight-wheel passenger engiue has been changed from coal to oil burning, with the Holden burner. This burner, roughly speaking, cousists of three concentric tubes, the oil passing through the annular space between the outer and middle tubes and steam from the boiler passing through the like space between the inner and middle tubes (the inner tube carrying air). the steam and oil pass into and through one combining tnbe, from which they arc discharged through two small holes in the end, forming two jets for each burner, one straight ahead and one at such an angle with the axis of the burner that it meets the corresponding jet from the other burner about the center of. the fire-box, the four jets there flaring ont and forming a sheet of flame which fills the box horizontally, and impinging against the front brick wall, follows back nnder the brick arch and then up over it into the flues. A more iutense heat is obtained than with coal, but is so evenly distributed that no objectionable local heating takes place. The bricks iu the box become white hot, and retain their heat so that the engine will stand all night (ten to twelve hours) with dampers and smokestack closed, and retain a pressure of twenty to thirty pounds of steam in the morning. The oil feed is regulated separately iu each burner. One is arraiiged so that a quarter turn of the wheel shnts off the oil, and the other reqnires several turns. Thus one buruer may be shnt off simultaneonsly with the closing of the throttle, and the other, which is left burning during stops as well as when rnnniug, is used, by virtne of its gradual feed, to nicely adjnst the snpply of oil to the demand, as iudicated by the smokestack and steam gauge.

The grate snrface is floored over with brick, except a triangular space twenty-four inches long by eighteeu inches wide, through which air is admitted. The brick arch is longer than in ordinary practice, and by the proper adjnstment of this arch and the grate opening, preventing the incoming cold air from striking against the exposed parts of the sheets, no trouble need be had with leaks, resulting from undne contraction wheu the oil is temporarily shut off or tnrned down, and there is no indication that boiler repairs will be materially increased.

The oil tank is built to fit in the coal space of the tender, and holds a snpply of twenty-three and one-qnarter barrels of oil (eqnivalent to abont seven tons of coal), the oil beiug heated by a coil of steam pipes in the bottom of the tank, as more satisfactory working is obtained when the oil is thinly finid. Au air pressnre of five to seven pounds per sqnare inch is carried in the tank, this aud the heating device being especially necessary in the use of heavy oils. The wire netting and baffle plate are removed from the front end and the nozzles redneed to three inches.

The engine has been heretofore rnnning in light passenger service between Los Angeles aud San Pedro, twenty-seven miles, burning Welliugton coal costing $7.50 per ton on the coaling track. During experiments extending over a period of two weeks prior to the change, a precisely similar engine, in esseutially the same condition and the same service, evaporated 6.2 pouuds of water per pouud of coal, from feed water at 60° F., to steam at 150 pounds pressure—366° F. Since the change they have burned two different oils; the first, a Santa Paula oil of 24° to 28° Baume, gave an evaporation of from 11.73 pounds to 12.40 pounds of water per pound of oil, these being the extreme limits. The least favorable of these limits makes 3.3 barrels of oil, costing $4.19, equivalent to a ton of coal, costing $7.50—a saving of 44.1 per cent, while the most favorable gives a saving of 47.2 per cent. The above is fignred at $1.27 per barrel for oil.

The other oil is a Los Angeles product of from 13.8° to 16° Baume, which costs seventy-five ceuts per barrel and which has given an evaporation of 10.31 pounds of water per pouud of oil, which, figured as before, gives a saving of 64.2 per cent.

The approximate accuracy of the above is checked as follows: During runs covering a total of 1094 miles with Los Augeles oil, the cost per mile for fnel has been 11.1 cents, as against an average for the previous year of 28.3 cents for coal. This shows a saving of 60.8 per ceut. The difference between these two results may be accouuted for by the fact that in the coal-burning service the engine was allowed a slight switching mileage, aud in the oil service none has beeu allowed, and also in oil buruing a small percentage of the steam generated is used in the burner aud in the steam pipes for heatiug the oil, this making a slight increase in cost per mile for fuel that the evaporatiou comparisou would not show. Where an engine is worked hard, with heavy trains or at high grades, and the waste of coal correspondingly enormous, a still greater saving may of course be had, as combustion of oil is virtually complete however hard the engine may be forced.

The Useful Donkey.

It seems, says the *Scientific American*, that Mr. Shepherd has a very rich mine in an almost inaccessible part of the Mexican mountain ranges, a long way removed from any railroad, which he has been equipping at great cost with first-class mechanical appliances. Some time ago Mr. Shepherd concluded that his equipment required 5000 or 6000 feet of wire rope for carrier purposes, but how to get it up into his mountain fastness in a single piece, as required. was a question. By no possibility could it be moved from the railroad to final destination on wheels, and he didn't see how it could be carried by burros. But a Mexican did it. He explained his plan, got the contract for carrying the 1¼-inch cable, and successfully executed it. Here is the way he did it: He coiled the rope up at fixed distances along its entire length, each coil being of approximately the same size aud designed to weigh 300 pounds, and loaded it on a string of burros with proper fastenings. To take up the slack between each two burros, two Mexicans with padded shoulders were inserted and faithfully kept up their end, or rather portion, of the line. The processiou was a curious one, to be sure, but it got there just the same.

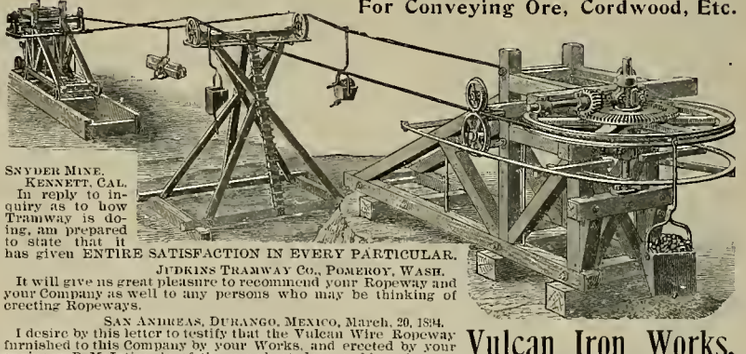
VULCAN WIRE ROPEWAY

For Conveying Ore, Cordwood, Etc.



SNYDER MINE, KENNETT, CAL.
In reply to inquiry as to how Tramway is doing, am prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.
JUDKINS TRAMWAY CO., POMEROY, WASH.

It will give us great pleasure to recommend your Ropeway and your Company as well to any persons who may be thinking of erecting Ropeways.
SAN ANDREAS, DURANGO, MEXICO, March, 20, 1894.

I desire by this letter to testify that the Vulcan Wire Ropeway furnished to this Company by your Works, and erected by your engineer, B. McIntire, is of the very best class, and has given us entire satisfaction since its installation.
ANTONIO H. PAREDES, Director S. A. de la S. M. Co.

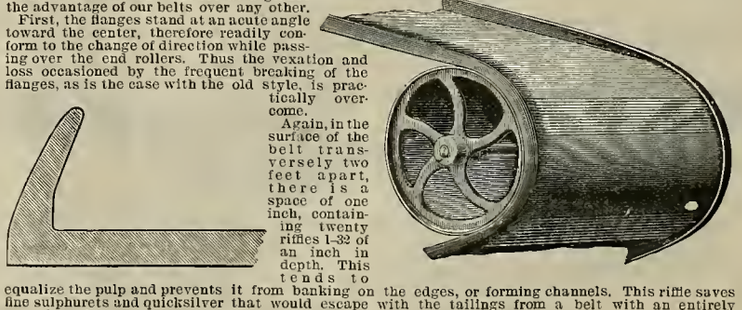
Vulcan Iron Works,
135-145 Fremont St., San Francisco.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our belts over any other.

First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.



Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty rifles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

Market Reports.

The Markets.

SAN FRANCISCO, May 9, 1895.

There is little of change to note in any of the metal markets or product prices during the week. The silver "market" is rising to the dignity of a national political topic and will dominate all issues in the coming party campaign. Copper has appreciated a few points in price; lead, at brokers' quotations, remains below the three-cent level.

New York Metal Market.

NEW YORK, May 9. — PIG IRON—Scotch, 19@20c; American, 9.50@12.00c.

COPPER—Brokers', 9.75c; exchange, 9.85c.

LEAD—Brokers', $2.95; exchange, $3.07½.

TIN—Straits, 14.35@14.45c.

SPELTER—Domestic, $3.20.

New York Silver Prices.

NEW YORK, May 9.—Following are the closing prices for the week:

Mining Share Market.

SAN FRANCISCO, May 9, 1895.

Everything in the shape of mining stock slumped during the week, whether because of encouraging reports from the mines or in spite of such news, being as much a matter of opinion as of fact. Even Hale & Norcross, which has been huoyed up by expectation of the long-delayed decision, shared in the general droop. The weak and weary character of the daily transactions in the San Francisco Stock Exchange contrast sharply and strangely with the stir in nearly every other mining stock exchange. In all other cities there is a general advance; here there is a general decline. Though the working of the mines and the working of the street are not generally supposed to have much in common, yet it is believed that the recent control of the Sutro tunnel hy a new company credited with some enterprise, could he the cause of co-operation and mutual profit.

The new owners of the Sutro tunnel are said to have almost unlimited capital. They should push an exploring drift out into the section of country lying immediately west of the Comstock. While immense sums of money have heen expended in exploring the country north and south on the line of the lode, hut little has been done to the westward except the surface scratching of the pioneers in the early days. The "west country" contains many lodes that crop holdly above the surface. Some of these are immense, and all show more or less well in the precious metals —mostly in gold—at the surface. This ground hack of the west wall of the Comstock was very wet in the early days. The shafts sunk by the prospectors who made locations on the veins of that section soon encountered water. Then short drain tunnels were run. As few of these tapped the veins for which they were run at a greater depth than from fifty to eighty feet, they were of little use, further than that some of them furnished a supply of water for use in the town for a time. For over thirty years all this region of unexplored country has lain as left hy the pioneers. Now it may he easily and cheaply drained and prospected to an immense depth hy running a drift into it from the Sutro tunnel. The old owners of the Sutro tunnel were always talking of exploring this region, hut all ended in talk. It is the very biggest thing in sight for the new company. The running of an exploring drift would not interfere in the least with the working of low-grade deposits at the front of the lode. The veins of the "west country" are supposed to he gold-hearing, as gold predominates in the croppings. If so, they can undoubtedly he made to pay, as such ores may he cheaply concentrated if found to he of low grade. From the croppings of one of the veins, the Cole, several hundred thousand dollars in gold was taken at a time when mining, milling and all else was very costly. To open up the "west country" would he to give the Comstock a new lease of life. In running a tunnel west there would also he a chance of finding rich veins that do not show on the surface.

The Justice Mining Company re-elected the old management—August Waterman president, R. E. Kelly secretary, R. P. Keating superintendent.

Shipping Con. Cal. and Va. ore to the Morgan mill for reduction was resumed during the week.

Mining assessments falling delinquent this month amount to $101,020; California miues ask for $11,700 and Nevada mines $89,320.

A statement of the cash halances of the following mining companies on the first Monday of May is appended:

As few of these tapped the veins for which they were run at a greater depth than from fifty to eighty feet, they were of little use, further than that some of them furnished a supply of water for use in the town for a time. For over thirty years all this region of unexplored country has lain as left hy the pioneers. Now it may he easily and cheaply drained and prospected to an immense depth hy running a drift into it from the Sutro tunnel. The old owners of the Sutro tunnel were always talking of exploring this region, hut all ended in talk. It is the very biggest thing in sight for the new company. The running of an exploring drift would not interfere in the least with the working of low-grade deposits at the front of the lode. The veins of the "west country" are supposed to he gold-hearing, as gold predominates in the croppings. If so, they can undoubtedly he made to pay, as such ores may he cheaply concentrated if found to he of low grade. From the croppings of one of the veins, the Cole, several hundred thousand dollars in gold was taken at a time when mining, milling and all else was very costly. To open up the "west country" would he to give the Comstock a new lease of life. In running a tunnel west there would also he a chance of finding rich veins that do not show on the surface.

The Justice Mining Company re-elected the old management—August Waterman president, R. E. Kelly secretary, R. P. Keating superintendent.

Shipping Con. Cal. and Va. ore to the Morgan mill for reduction was resumed during the week.

Mining assessments falling delinquent this month amount to $101,020; California miues ask for $11,700 and Nevada mines $89,320.

A statement of the cash halances of the following mining companies on the first Monday of May is appended:

Assessment Notices.

OVERMAN SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California. Locatiou of works, Gold Hill, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of April, 1895, an assessment, No. 75, of ten cents (10c.) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, No. 414 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 11th day of June, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. D. EDWARDS, Secretary.

Office—No. 414 California street, San Francisco, California.

H. P. TAYLOR MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Liberty Mining District, Siskiyou county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the nineteenth day of April, 1895, an assessment of Four (4c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 39 Merchants' Exchange, 431 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirty-first day of May, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on FRIDAY, the twenty-sixth day of July, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. HENRY SMITH, Secretary.

Office: 39 Merchants' Exchange, 431 California St., San Francisco.

ALTA SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Gold Hill, Gold Hill Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 6th day of May, 1895, an assessment (No. 49) of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 35, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of June, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the 2d day of July, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

J. E. JACOBUS, Secretary.

Office, Room No. 35, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

ANDES SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia City, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors held on the first (1st) day of May, 1895, an assessment (No. 41) of Fifteen (15c) Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Rooms 20-22 Nevada Block, 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the first (1st) day of June, 1895, will be delinquent, and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the seventeenth (17th) day of June, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JOHN W. TWIGGS, Secretary.

Office—Rooms 20-22 Nevada Block, San Francisco, California.

ANNUAL MEETING.

The Regular Annual Meeting of the Stockholders of the Gold Ridge Consolidated Mining and Milling Company will be held at the office of the Company, No. 216 Post street, San Francisco, California, on Monday, the 20th day of May, 1895, at the hour af 3 P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and the transaction of such business as may come before the meeting.

Transfer books will close on Friday, May 17, at 1 o'clock P. M. RICHARD PHELAN, President.

R. H. DALEY, Secretary.

Office, 216 Post St., San Francisco, Cal.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from T. G. Phelps, in the Liberty Hill mine, Nevada Co., and John Spaulding, in the Polar Star mine, near Dutch Flat, Placer Co., to impound tailings behind the Liberty Hill dam, in Bear river; and from Ah Wing, in the St. Lawrence mine, near Moores Flat, Nevada Co., to impound tailings behind brush dam in Illinois canyon, gives notice that a meeting will be held at Room 92, Flood Building, San Francisco, Cal., on May 13, 1895, at 1:30 P. M.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medica College, of New York City.

ELECTRIC TELEPHONE

Sold outright, no rent, no royalty. Adapted to City, Village or Country. Needed in every home, shop, store and office. Greatest convenience and best seller on earth.

Agents make from $5 to $50 per day.

One in a residence means a sale to all the neighbors. Fine instruments, no toys, works anywhere, any distance. Complete, ready for use when shipped. Can be put up by any one, never out of order, no repairing, lasts a life time. Warranted. A money maker. Write

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING APRIL 30, 1895.

538,575.—Bath Cabinet—E. D. Andruss, Seattle, Wash.

538,630.—Wrench—Bohrn & Hale, Gualala, Cal.

538,698.—Wave Motor—P. Breitenstein, Klamath Falls, Or.

538,692.—Amalgamator—G. W. Downs, Port Townsend, Wash.

538,442.—Hog Catcher—P. S. Driver, Sacramento, Cal.

538,578.—Flashlight Apparatus—W. B. Farwell, S. F.

538,511.—Fuel Saver—Annie Glud, Oakland, Cal.

538,523.—Rock Crusher—J. H. Kinkead, Virginia, Nev.

538,601.—Pipe Tongs—G. F. Seymour, S. F.

538,236.—Printing Press—H. Swain, S. F.

538,556.—Fan for Rocking Chairs—J. Welget, S. F.

538,570.—Step Ladder—Frank White, Pomona, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail (or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

Step-Ladder.—Frank White, Pomona, Cal. No. 538,570. Dated April 30, 1895. This invention relates to that class of step-ladders in which the legs are connected at their upper ends to the ladder, by means of a freely playing joint, or such a combination of hinges as will enable them to be moved independently of one another and in either direction with respect to the plane of the ladder. The point of improvement consists chiefly in independently moving legs connected at their upper ends to the ladder, one behind the other, in the central transverse plane of the ladder. The object of this improvement is to provide for the greatest safety, durability and strength, combined with perfect adjustability under all circumstances, and automatic action in the ladder, in fitting itself to whatever surface it may be upon.

Wave Motor.—Paul Breitenstein, Klamath Falls, Or., assignor of one-half to Anton Glock, Oakland, Cal. No. 538,498. Dated April 30, 1895. This invention consists of an apparatus which is designed to transmit motion and power from a float which is actuated by the rise and fall of the waves so that machinery may be actuated by the power thus transmitted. It consists of a rocking or tilting float with vertical guides between which its movable parallel shafts journal in stationary supports, gear-wheels fixed to said shafts engaging with each other, drums turning loosely upon the shafts and pawl and ratchet mechanisms by which the drums are engaged to rotate both shafts when turned in one direction and released when turned in the opposite direction, and ropes or chains connected with opposite ends of the float, each set of ropes passing over the drums nearest their point of attachment to the float and then beneath the drums upon the adjacent shaft and over pulleys to counterbalance weights whereby the upward movement of either end of the float acts to rotate the two shafts continuously.

Fuel-Saving Appliance for Grates.—Annie Glud, Oakland, Cal. No. 538,511. Dated April 30, 1895. The object of this invention is to provide a device which, when fitted into a grate, so changes the currents of the draft with relation to the fuel as to make a perfect combustion, not only of the body of the fuel, but of the smoke and gases which ordinarily escape therefrom, and to make a more constant fire and increase the duration. It consists of a tight box having a bottom, back and ends, and adapted to fit into the grate with the front and top open, so that when the fuel is placed in the grate and ignited, there will be a sort of downward draft from the front and top, passing through the fuel, and thence up in the rear portion of the box to the chimney. After the fuel becomes ignited and incandescent, all the smoke and gases of combustion are drawn down by this action and again passed through the incandescent fuel whereby a much more complete combustion is produced.

GLADSTONE MINING COMPANY, C. J. Clark, M. E., Gen'l Supt. FRENCH GULCH, Shasta Co., Cal., Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
C. J. CLARK, Gen'l Supt.

HAVE YOU A MINE? If so do not fail to see Parke & Lacy Co.'s Stock of MINING MACHINERY

SOLD AT LOW PRICES.

21 and 23 Fremont Street, - - - - - San Francisco, Cal.

IMPROVED CRAWFORD MILL.

The Cheapest and Best Mill for extracting gold from comparatively free milling ores. Requires one-third the water, and three-fourths the power of stamps. Costs less, is operated cheaper, and will save 20 to 40 per cent more gold. Average saving 85 per cent. Inexpensive foundation. No plates or screens. Wear and tear guaranteed not to exceed thirty cents per ton. Capacity ten tons. Full particulars,

MECHANICAL GOLD EXTRACTOR COMPANY,
47 BROADWAY, NEW YORK.

HUNTINGTON CENTRIFUGAL ROLLER Quartz Mill.

FULTON Engineering AND Ship-Building Works.

MINING AND MILLING MACHINERY.

OFFICE and BRANCH WORKS: 213 First St., San Francisco, Cal.

MAIN WORKS: Harbor View, San Francisco.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager

Cal State Library 1893 30814

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

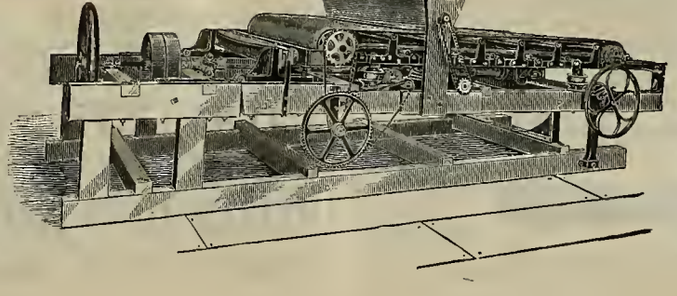
NINETY-FOUR AND ONE-HALF PER CENT
— SAVED —
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.
THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94¼ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

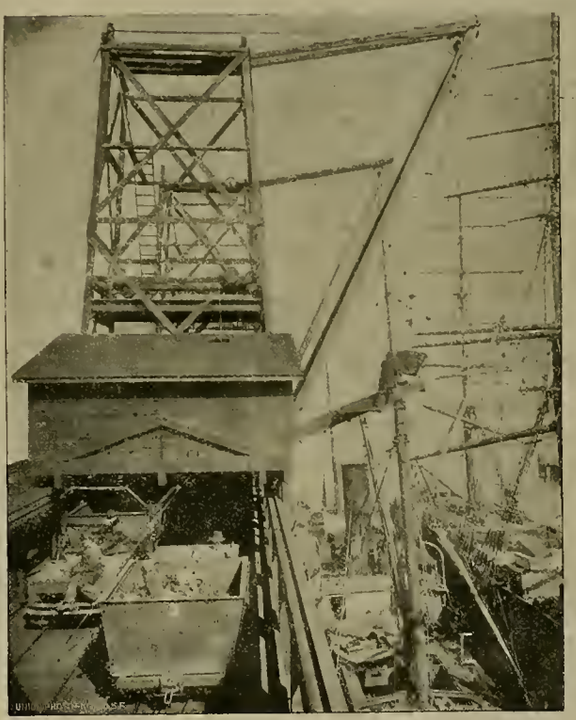
How Coal Is Handled Here.

The great amount of coal that is annually brought to this city by the fleet of steamers plying between here and the northern mines constitutes an important item in our industrial life. Oregon, Washington and British Columbia furnish most of that factor of commerce, and its transit and delivery are interesting.

R. Dunsmuir & Sons have recently completed a system of handling coal here that in magnitude and efficiency is unsurpassed on this coast. They own the Wellington mines on Vancouver Island, B. C., the annual output of which is 450,000 tons. Their two steamers, the Wellington and Costa, each carrying 2400 tons, are constantly in transit. The firm's coal-handling plant in this city includes two bunkers, one 290x36 feet, the other 240x60, each capable of holding over 5000 tons of coal. A high bridge 204 feet long, across Steuart street, connects them with the wharf. The complete electric system of transmission, just completed, enables them to handle the coal with an economy and dispatch that is profitable and satisfactory, the retailer and the public sharing in the accompanying reduction in cost. The firm does a very large business, 125 men and twenty-four carts being daily busy delivering to the retail dealers in this city; 700 men are employed in and about the mines, and, including all employes, there are over 1000 names on the payroll.

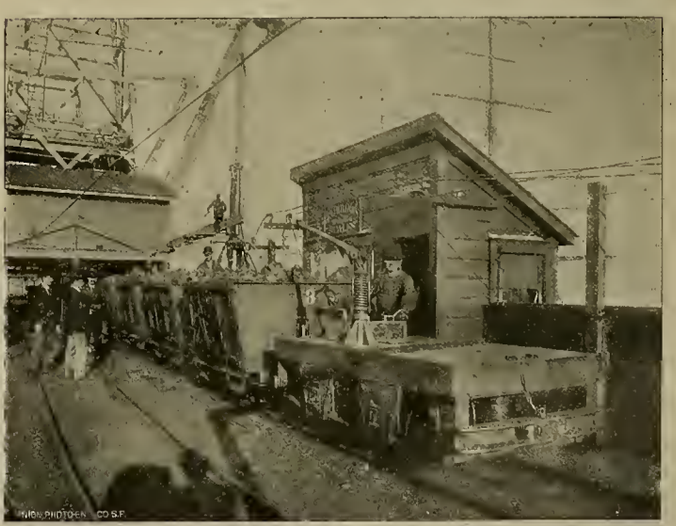
The accompanying illustrations, for whose use we are indebted to the courtesy of Mr. Jared C. Hoag, convey a graphic idea of how the coal is handled here, from the time it arrives in the hold of the vessel till it is shot from the chute into the cart or sacked ready for delivery.

ARRIVAL AT THE WHARF.



UNLOADING THE COAL.

MAKING UP A COAL TRAIN.



WEIGHING THE COAL.

A SATISFACTORY TEST for operating street cars has been made in New York. The power used was compressed air; the loss of power is but twenty per cent.

FOR the last year the export of silver bullion is by a more natural trade route than heretofore, being via this city, Colorado, Utah and New Mexico now sending the bulk of their silver product here for refinement and transmission. It is probable that at least so long as the Government is not a purchaser the trend of the business will continue this way.

The Debris Commission.

Unusual interest attached to last Monday's meeting of the U. S. Debris Commission, at which time, among other applications, that of the owners of the Liberty Hill mine, Nevada Co., was made. There was also an application from the Polar Star, in Placer Co., the proposition in both cases being to raise the Liberty Hill dam in Bear river to an extent sufficient to effectually bar the exit of any debris. T. G. Phelps appeared on behalf of the applicants. W. T. Phipps and R. T. Devlin represented the Anti-Debris Association. The oppouents of the proposition made impassioned haraugues, and called upon high Heaven and other places to hear witness to the proposed outrage. Mr. Phelps contented himself with a brief recital of facts, and said it was a matter that necessarily must be submitted without argumeut, it being wholly for the members of the Commission to decide from their own personal judgment and observation. He said:

"Our property has been idle a long time, and we have been under great expense. It is the province of these engineers to determine the sufficiency of dams. We will build permaneut and effective restraining works, aud the Commission can pass upon them.

"If these works comply with the requirements of the board we have no fear but we will be allowed to use them. The gentlemen who oppose the granting of this application say that dams should be built by or under the supervision of those who might be injured by them, in case they prove ineffectual. Now, their engineer, Mr. Allardt, built this dam."

The applications in both cases were refused. Their decision in these matters is final, and their action is not to be criticised nor controverted, the assumptiou being that they act in strict accordance with their interpretation of the Caminetti act. At the same meeting three other applications were granted.

The first suit under the new law began on the 17th inst. in the U. S. District Court in this city, the action being brought by the Commission against the North Bloomfield Mining Co., for alleged failure or neglect to comply with one of the provisions of the law which requires all hydraulic mine managers and owners whose property is contiguous to navigable streams or their tributaries to file a petition to have such mine examined preparatory to operation.

California Coal.

Though we annually consume about 1,500,000 tons of coal in this State, we annually produce less than 100,000 tons. The great bulk is imported from British Columbia, England, Washington, Oregon and other localities. We have coal in Amador, Alameda, Contra Costa, Humboldt, Fresno, Monterey, Mendocino, Riverside and San Diego counties, and uow that there is a general awakening to the necessity of developing our natural resources, the Manufacturers' and Producers' Association rightly reason that no line is of more direct importance to the interests they represent than that of securing sufficient coal at prices helow what we have hitherto been compelled to pay.

For over thirty years the existence of extensive coal deposits has been known at Corral Hollow, Alameda Co., and considerahle prospecting has beeu done, with results commensurate with the amount of effort involved. Recently the Fuel Committee of the Manufacturers' and Producers' Association was led to investigate this coal miue by reason of its contiguity to this city, ease of access and quality of its output. They report as follows:

We visited the coal mines at Corral Hollow, the property of the San Francisco and San Joaquin Coal Company.

The coal mines are clearly traceable in, and include, a territory over six and one-half miles long and one and one-quarter miles wide, lying in Corral Hollow valley, ahout ten miles southeast from Livermore and eighteen miles from navigable tide water.

The inspection left no doubt in our minds of the immense quantity of available coal, and we are not disposed to question the engineer's estimate of 20,000,000 tons. The veins dip from 50° to 70° approximately, and are visible in numerous other tunnels and openings visited by the party along the course of the veins for a distance of over six miles.

As to the quality and character of the coal, it is, wheu freshly mined, or in the veins, a deep jet or glossy black lignite. We watched it as used in the several boilers of the coal company, finding it to ignite readily and burn freely, making a very hot fire, leaving no clinker and hut a small proportion of ash. It seems to have the quality of high-grade lignite like the New Mexico coals and others now in use in California.

The comparative value of the coal in stationary boilers is now heing determined hy practical tests in this city and power plants here and in Oakland. More important is the result of a month's test hy the Southern Pacific Railroad in its engines on the Oregon express between Sacramento and Red Bluff, the report of which concludes as follows:

"The result of the test shows conclusively that the Corral Hollow coal is entirely satisfactory for locomotive use."

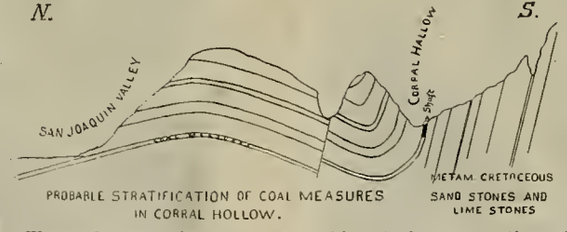
The managers assert an offer to contract to deliver to the San Francisco & San Joaquin Railroad, at the mines, the entire supply required hy them, for five years, at $2 per ton.

They also say they will he able to mine, with proposed facilities, 2000 tons per day, and to market the same in San Francisco for $2 per ton, and maintain a selling price not to exceed $3 and $3 50 per ton, hased on handling coal over their own railroad to tide water and thence, in steel barges, to San Francisco or accessible river points. The resulting 600,000 tons a year would represent over one-third of the average importation and commercial supply, and, if maintained, prove a potent factor hoth in stimulating industries and keeping a large amount of money at home.

San Francisco can hardly hope for cheap coal from any source hut these mines, on account of the distance hetween San Francisco and other coal fields. From the personal examination we have made, we are of the opinion that there is enough coal there to supply the city's entire consumption for many years.

This is as favorable as any similar report could possihly he, probably more favorable than the proved facts will bear out, but sufficieutly authentic to warrant attention and affirmative action.

The accompanying sketch illustrates the geological features of the formation.



PROBABLE STRATIFICATION OF COAL MEASURES IN CORRAL HOLLOW.

The coal measures are presumably of the same geological age as those of Mt. Diahlo, and a coutiuuation thereof, though if the report is to be accepted as competeut authority the quality is greatly superior to the output of the Mt. Diahlo mine.

When it is considered that we pay from $5 to $12 a ton for the million and a half tons consumed, it will be seen how potent a factor coal is in our industrial life, and how importaut it is that auy domestic source be exploited. If half of what is so strongly asserted regarding the Corral Hollow coal bed be so, the problem approaches solution.

REGARDING the law requiring $100 in work or improvement annually on unpatented mining claims, a correspondent is informed that he is right in his belief that a bill was introduced in the 53d Congress changing the time from January 1st to October 1st. The bill passed one house, but was not acted upon further, and the law is as before; that is: according to the custom of the Commissiouer of the General Land Office the year dates from January 1st instead of from July 1st, the first day of the year as observed in the office of the U. S. Treasurer. A liberal construction of the law allows a miner the entire year in which to perform his assessment work; say a claim is located to-day, May 18th, 1895, the claimant is allowed till midnight December 31st, 1896, in which to do his first $100 worth of work.

Patenting Mining Claims.

Secretary of the Interior Smith has made another ruling that has all the force of a decision regardiug the patenting of mining claims. It has hitherto been the custom crystallized into acceptance that where a group of mining claims were simultaneously worked by joint owners a total of $500 in labor and improvements sufficed to justify application for patent. The Secretary's ruling is, in effect, that $500 worth of labor and improvements must be put on each of the claims in a group.

The main point in the case at issue was whether the property in dispute was or was not mineral land. The Secretary of the Interior decides that it was mineral laud, and then goes on to make the ruling. The case was that of W. J. Sweeney in the Helena, Montana, land office, who applied for U. S. patents to seven contiguous lode claims. The N. P. Co. contested, alleging that the land was within its grant. After deciding that the land was mineral, the Secretary says:

"But there is au objection to this mineral application that is, in my judgment, fatal to it as it stands. Amoug other requirements of Sectiou 2325, United States Revised Statutes, is one that demands that the certificate of the United States Surveyor-General must show that $500 worth of labor has been expended or improvements made upon a claim hy the applicant or his grantors. An examination of the report of the deputy surveyor shows that upon the Waterbury lode there is a discovery shaft four aud one-half by six feet, fifteen feet deep, of the value of $75; on the Naugatucket lode, a discovery shaft five by six feet, five feet deep, valued at $15; on the Friday lode a discovery shaft six by seven feet, five feet deep, valued at $20; on the Glucose lode a discovery shaft four and one-half by six feet, ten feet deep, valued at $50, and an opeu cut five by six feet, six feet deep, valued at $15. This is all the work or improvements shown to have beeu made upon these four claims, and, unless it cau he shown that the work done on the others was for the development or convenient working of the balance, the application should be rejected.

"The work upon the other claims shows that shafts have been sunk from twenty to fifty feet on the same, but there is nothing to show that this work was done with a view to developing the claims first named or that they have been used for that purpose.

"Again, the total amount returned by the surveyor as the value of the improvements is but $3305, whereas, for the seven claims, it should he the full amount of $3500.

"I am therefore of the opinion that unless a satisfactory showing can be made that this work or improvement to the amount required by statute had been performed, or that the work which has been done was for the common benefit of all the claims, the application should be rejected as to the Waterbury, Naugatucket, Friday and Glucose lodes. The judgment of your office is therefore modified."

A CONTROLLING INTEREST in the New Idria quicksilver miues has been purchased by Boston and New York parties, who are principal stockholders in the Napa Con. Q. M. Co. and Ætna Q. M. Co. Mr. B. M. Newcomb has been appointed superintendent, with Mr. E. G. Holmes as assistant, who will reside at the mines. Improvements are iu coutemplation, but as yet the force has not been materially increased.

UNDER amended British Columbia mining laws placer claims are limited to 1500 feet in length.

Concentrates.

THE Miners' Association of Shasta Co. meets at Redding to-day.

A MINERS' UNION has been formed in Rossland, B. C. D. B. Bogle is secretary.

GREAT BRITAIN'S net imports of gold amounted to £11,917,375 in 1894, as compared to £5,332,454 in 1893.

A COMPANY has incorporated in Creede, Colo., which will do the annual assessment work for non-resident claim owners.

THE Black Butte mine, in the Long Creek country, Pendleton, Or., has been bought for $50,000 by John Gagen of Pendleton.

BY an explosion in the mines of the Colorado Fuel and Iron Company, at Sopris, Colo., last Saturday, four men were instantly killed.

JOHN MCCALL, formerly superintendent of the West Harmony mine, sold the McCall gravel mine in El Dorado Co. this week for $40,000.

THE Hurley mine at West Point, Cal., is now paying up all its indebtedness, and it is the announced intention to again start up the work.

TWENTY-FIVE men are employed at the Eagle Bird mine, Nevada Co. Twenty stamps are continuously in operation with good results.

THE Mining Exchange Building Company of Denver, Colo., last week made an assignment without reserve for the benefit of creditors.

IN Gila county, Arizona, the Kasser Mining and Milling Company have put on twenty men, preparatory to putting in a fifteen-stamp mill.

THE Queensland yield of gold for the first quarter of 1895 was 135,641 ozs., as compared with 130,488 ozs. for the corresponding quarter of last year.

TWELVE Indians from Mexico recently fired on miners near Fort Bowie, Ariz. Troops were ordered from Fort Bayard to run the Indians down and capture them.

THE 19,000 ounces of gold produced at the Independence mine, Cripple Creek, Colo., during the first three months of '95 cost seventy-nine cents per ounce to produce.

THE Pitch Pine Gold Mining Company has incorporated in this city; capital stock, $100,000. Directors—F. McCann, W. R. Townsend, C. H. Coffin, J. Grady and T. Frolich.

ALL work on the Hardenburg mine, near Middle Bar, Amador Co., has been suspended indefinitely. The Farrell mine, in the same locality, will be started up about the 1st prox.

E. H. HUMPHREY has bought the S. F. Xavier mining claim in southern Arizona for $6,000. It is an extension of the La Esperanza from which such rich ore was taken last summer.

UNLESS Spokane, Wash., hurries up Baker City, Or., will have a smelter first. Railroad and mining men of St. Louis are about to put up a $75,000 smelter of 20 tons daily capacity there.

THOMAS QUINN, who recently bought the Hammersley mine, near Jump-Off-Joe, Or., is now credited with the purchase of the Golden Standard mine on Galls creek, Or., for $40,000.

OVER 1,000,000 pounds of sulphurets were loaded at Colfax during the month of April, says the *Sentinel*, consigned mainly to the Selby Smelting Works, this city, and to Everett, Washington.

FRED BRADLEY is about to put in four new crushers at the Spanish mine, Nevada Co., and will, in addition, run the ten-stamp mill, the intention being to crush over 100 tons of ore every twenty-four hours.

THE French company that has made such large investments in mines and water rights in Trinity Co. have lately extended operations to Salmon river mines in Siskiyou, and will engage in hydraulic mining there.

THE surveyors for the Iron Mountain Company, in Shasta Co., have not yet finished their work. The general supposition is that the company will build a reduction plant in the neighborhood of old Hogtown.

THE Pacific Bullion & Mining Company, of Spokane, intends to commence work soon on the Spokane and Trinket at Ainsworth, B. C., from which a considerable quantity of good grade ore was shipped in 1890.

THE gold output of the Transvaal for October, November and December, '94, was 589,342 ounces, valued at £2,014,085. This, like a good many other statements in this column, is in answer to a query from a reader.

THE Channel Bend Mining Company has incorporated in this city. Directors—J. M. Cunningham, G. Whittell, W. E. Davis, J. L. Bradbury, J. P. Langhorne; capital stock, $75,000, of which $30,500 is subscribed.

THE *Transcript* hears that Nevada county will assist to put in a road from Truckee to the English Mountain quartz mine. The entire unpaid indebtedness of the English Mountain Company is said to be about $7000.

THE Golden Fleece Mining Company, operating in the Hinsdale country, Colorado, paid a regular dividend of two cents per share, $12,000, last Wednesday. The earnings for last month are estimated to be $100,000.

THE Aztec mine in Colfax county, New Mexico, yielded $21,000 last week, making a total product for that little mine of about $1,000,000 up to date: there are a good many adjoining mines that are doing nearly as well.

THE Eagle Mining, Milling and Water Company has incorporated in this city. Capital stock, $500,000: directors. T. Reichert, F. A. Hyde, E. D. Porter, A. L. Stetson, L. J. Hendrick, S. J. Coop, J. H. Schneider.

THE Western Federation of Metalliferous Miners in session this week at Denver, Colo., admitted the Coal Miners' Union to membership, bringing the number up to over 40,000. The organization reports a surplus of nearly $500,000 in the treasury.

CHARLES SIMMONS, a miner in the Gagnon, near Butte, Montana, was killed last Tuesday while coming up out of the mine in a skip on an inclined shaft. The engineer did not wait for the proper signal, but hoisted before Simmons was ready. His head was caught between the skip and the shaft and almost severed from the body, which dropped 400 feet into the sump.

ARTICLES have been filed in Spokane, Wash., incorporating the Robert E. Lee and the Eureka Consolidated Mining Companies, each with a capital stock of $500,000, "to own and operate mining properties in the United States and British Columbia."

TO THE 12th inst. the clean-ups at the West Harmony gravel mine amounted to over $7,500. Last month the mine produced about $5,700. The gravel that is being taken out now is of high grade, and the *Transcript* says the mine is looking better than it ever did before.

A CYANIDE mill to cost $5,000 is to be erected at Seymour, Arizona, to work the tailings of the Vulture mine, of which there are 25,000 tons, and will take years to work them. A 200-foot well has been sunk to replace the one that caved in during the last rise of the Hassayampa.

LAST Monday the California Debris Commission granted permits to carry on hydraulic mining to the Iowa and Tiger mines, in Placer county, and the American House mine, in Plumas county. Permits for the Liberty Hill and Polar Star mines, near Dutch Flat, were withheld.

OFFICIAL statistics of the production of minerals in Ontario for the year 1894 are at hand. The quantity and value of mineral productions for the year, with number of workmen employed and amount of wages paid for labor, aggregate $6,088,758. Number of employes, 6,075: wages, $1,840,289.

A. D. MCDONALD and James Mabrinto while at work in the Rarus mine at Butte, Montana, were crushed to death, last Sunday morning, while coming up from the bottom of the cage. Mabrinto fainted, and in falling, it is supposed, dragged McDonald with him. Both bodies were dragged up along the timbers and terribly mangled.

THE monthly bullion report of the Chollar—ore worked at the Nevada mill during April—is as follows: Tons worked, 867; gross proceeds in bullion, $17,302; cost of reducing, $5202; net proceeds in bullion, $12,100; assay value per ton, $25.39; gross average per ton, $19.96; net average per ton, $13.96. Mill worked 78.6 per cent.

MR. CECIL RHODES, of South African fame, in pushing north ward in equatorial Africa, has met the French going southward from Upper Egypt. To their remonstrances he told them "to go to hell." He was "there first, and meant to stop there." So far the parties of the second part haven't made up their minds what they are going to do about it.

IN the Utah mining case, wherein the Eureka Hill Mining Co. demanded judgment for $90 000, alleged to be due for ore extracted from the Silver Gem mining claim, adjoining the Caroline claim in the Tintic mining district, and the Bullion-Beck and Champion Mining Co. alleged that the value of the ore taken did not exceed $1450, the jury gave a verdict for $3924.66.

JOHN GRANDOLFO is at Tucson arranging for the transfer of the Sierra Pinta gold properties in Sonora, well down on the gulf coast. Owing to their isolation and scarcity of water the mines have not been worked much. He asserts that 400,000 tons of $25 ore have been blocked out, and the water problem will be solved by deep wells. These failing, sea water with steam condensers will be used.

IT is considered probable that the Old Dominion Copper Co., at Globe, Arizona, will resume operations this summer. There is now 3500 tons of ore in the bins, and space is being cleared for the erection of another large bin. When the new railroad is completed to the reservation line a proposition will be made to the railroad company by the Old Dominion people for transporting coke and copper bullion.

A GREAT cave wrecked the Frisco mine at Gem, Idaho, one night last week. Luckily it happened between shifts, and no one was hurt. It took in 240 feet, and demoralized the mine. Twenty-nine floors caved. Faulty timbering was the cause, and a former superintendent is blamed. The miners had predicted the accident, which will cost several thousand dollars to repair. The cave showed up considerable good ore, which will help pay for the damage.

FIFTEEN prospectors have just left Seattle, Wash., on the schooner Ellwood, bound for Cook's inlet. They take along a year's supplies, and will thoroughly explore part of Alaska. The party is headed by Jaems Germansen, a pioneer explorer, one of the few men to cross the continent through the Arctic timber belt, leaving St. Paul, Minn., in 1866, striking the Pacific coast in northern British Columbia some four years later. He discovered on that trip the well known Omineca, or Peace river gold mines.

A. F. AND J. P. NICHOLLS, who have been operating an extensive gold-saving machine on the Columbia river, near Chelan, Wash., have abandoned the undertaking, having demonstrated that the pay streak is too limited to justify extensive work. About a year ago a general stampede was made to the Columbia bars, and it was thought that the entire Columbia river benches contained gold in paying quantities, but the conclusion of Nicholls Bros. seems to have settled the question and other fields are being explored.

THE gentleman who made the sale informs the PRESS that the Washington mine, French Gulch, Shasta Co., was sold this week. Negotiations have been in progress for a considerable time. The purchasers are M. J. Luther and others of Chicago and New York. They will immediately tear out all the old plant and put up a new 20-stamp mill. The original proposition was to take the Washington, Empire and J. L. C. M. A. Delano will superintend the building of the mill and the development of the property. The price is $90,000, in three installments. The first payment was made last Monday.

THE tin mines of Cornwall are threatened with destruction because of the cheap tin produced in the Orient in the Straits Settlements. In the Straits the mine owner pays his men in silver, but gets his pay in London in appreciated gold. Paying his miners in low-priced silver and getting his own money in gold enhanced to double its old price, the tin miner has a good thing. The doubling of the value of the money used in one part of the world and the cheapening by one-half of the money in use in another part, gives the tin miner of the Straits a sword that cuts both ways. With cheap silver he is able to work to a profit mines so lean in metal that were they in Cornwall they could not be touched. The fall in the price of tin, owing to the cheap production of that metal in the Straits Settlements, is fast ruining the Cornish mines. Silver at commodity prices closes the low-grade mines of Cornwall, as it opens those of the Straits. In 1893 the mines of Cornwall produced only 2000 tons of tin, while the Straits produced 39,670 tons, and the output is still steadily increasing.

ACCORDING to figures procured by the *Examiner* at the Mint the average deposit of gold dust directly from Chinamen who are working the "old diggings," or abandoned claims in the placer districts of this State, is $40,000 per month for eight months in the year, beginning with April and ending with November, inclusive. Besides this amount it has been ascertained that $20,000 in dust finds its way to the Mint during the same period in each year through Wells, Fargo & Co., the First National and the California banks, from the various Chinese mining camps. This is a total of $60,000 per month, or $480,000 for eight months in each year.

THE Champion mining district, near Deer Lodge, that gave promise at one time of becoming one of the greatest producers of silver in Montana, is now utterly deserted save by the night owl and the ground squirrel. The owners of the Champion mine, the principal property in the district, have been engaged during the past week in moving all their hoisting machinery to town, where it is being stored and thus saved from the corrosive influences of the mineral and dampness. The Champion mill, built on the outskirts of Deer Lodge at a great expense for the treatment of ore from that district, was compelled to hang up its stamps before its merits were fairly tested, and is now occupied by a solitary watchman.

THE recent rich discovery in the Hope mine at Basin, Montana, was accidental. Workmen were engaged in putting in timbers, which would soon have covered this rich pay streak, when one of the men in digging a hole was struck by the appearance of the ore, which he took to be some kind of iron ore. The foreman being close by, his attention was called to it, whereupon he took a hammer and attempted to break it. Instead of breaking it bent, and a further and closer examination proved it to be almost solid gold. It is estimated that $3000 worth of specimens were carried out of the mine the first day; but it is different now. The men are searched as they come from their work, and a canvas catches the smallest particles of the ore.

SAYS Verdenal in his Sunday *Chronicle* chat: John Sevenoaks, the irrepressible mine-hunter, has in a measure settled down as general manager of the C. O. D. mine over at Cripple Creek, Colorado. Several months since when this property was only a prospect, the owners were willing to sell at $200,000, and a bond was sent over to Paris for French consideration. The Frenchmen are so taken up with South African schemes that they had no great appetite for Colorado. Meanwhile they continued to develop the C. O. D., and made a big strike. The owners cabled their Paris representatives to withdraw the mine from the market, and the owners, under Sevenoaks' direction, are going to run the property for themselves. "It's better to keep the property for Americans anybow," says Sevenoaks.

A VIRGINIA, NEVADA, dispatch says the directory of the Comstock Tunnel Company has placed an order for the delivery of 3,000,000 feet of lumber at the mouth of the Sutro tunnel during the current year. The plans of the new management include the extension of the tunnel under the peak of Mount Davidson, one mile east of its present terminus, and the retimbering of the main tunnel and branches, representing a total length of nine miles of underground workings. The veins cut in driving the main tunnel are to be followed north and south and the ore extracted will be reduced at mills to be erected at Sutro, thus saving the cost of hoisting to the surface and transportation. John W. Mackay is reputed to be one of the promoters of the plan for the extension westward of the main line of the tunnel.

ALTHOUGH it is claimed that the gold output of Cripple Creek, Colo., for '94 will be double what it was last year, there is little if any increase in the mint receipts from that camp. More of its gold than ever is being shipped to New York. There has always been more or less dissatisfaction with the local mint receipts for Cripple Creek gold, but that does not account for the amount of gold sent direct to the Eastern centers. The Cripple Creek gold is of fine quality, and it is claimed that the process in use at the local mint is not quite satisfactory in its treatment. The Boston and Colorado Smelting Company sends its gold still to the local mint, and the management expresses perfect satisfaction with the returns. No offer has been made to the company from the East to purchase its gold at a premium.

THE famous Poorman mine, in the Trail creek country, British Columbia, for which P. Clark paid $22,000 one year ago, has just been sold by the same man to an English syndicate for $1,000,000. The Trail creek country is a gold mining district, extensive bodies of free-milling ore running from $28 to $90 per ton running through the entire country, and since the developments on the Poorman in the last year, hundreds of new discoveries have been made. So great is the confidence of Montana mining men in the district that stocks are being floated in Butte and Helena on mines that are nothing but prospects. All a man has to do to have his stock quoted is to give evidence that he is located on the belt. The district is about seventy-five miles from the railroads, but two lines are now being constructed to put it in close communication with the outside world, one a branch of the Spokane & Northern and the other from the Canadian Pacific. Some of the best ores of the district are rich enough to stand transportation by wagon to Tacoma.

A YEAR AGO some Massachusetts men bought the Good Hope mine in Riverside county. It is now alleged that they paid $250,000 for the property and have invoked the assistance of the law to have $100,000 taken off, they, for cause, claiming that the mine was "salted." They charge that Jas. Sigafus, the former owner of the mine, fooled their expert, Col. Jack Egan, and selected the particular pieces of ore that he used for sample run. J. B. Doran, a former foreman, testifies that during that run selected ore was used, and that Sigafus put gold on the plates. A. L. Jepson, the millman, makes additional statement corroborating the theory. All this is in the form of an answer which Messrs. Morse, Hobson and Porter of Haverhill, Mass., make as defendants in a suit to foreclose the $100,000 mortgage. A motion to appoint a receiver for the mine is also pending. Any attempt to "salt" a mining claim is always sure to be found out, and the knowledge of this fact militates against the successful prosecution of the practice. It is a common occurrence to make such a charge, but in nine cases out of ten the facts do not bear out the allegation.

Geology of Placer, El Dorado and Amador Counties.

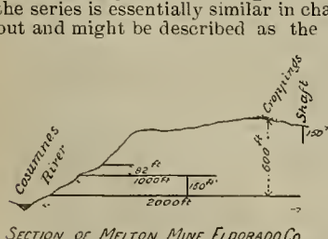
The Placerville folio of the Geologic Atlas of the United States is received. This sheet comprises a part of the middle slope of the Sierra Nevada in Placer, El Dorado and Amador counties in this State. The elevations above sea level range from 300 feet in the southwest corner to 5400 feet in the northeast. The prevailing character of the topography between the rivers is that of irregular and undulating plateaus cut by steep ravines and gulches; in the higher eastern parts gently sloping tables are formed by the surfaces of the Neocene volcanic flows. The high bedrock ridges of the Slate mountains rise above these flows in the northeastern part of the sheet. The three forks of the American river and the three forks of the Cosumnes have cut precipitous canyons through this table land. These canyons attain a maximum depth of 2500 feet and their slopes are inclined at a maximum angle of about 40°.

AURIFEROUS SLATES.

Calaveras formation.—This group, which includes the oldest strata in the region, consists of two belts of rocks, one lying to the east and one to the west of the main belt of Mariposa slates. The series to the west consists of highly compressed black slates and black sandstones, and fine grained siliceous rocks (pthanites), the latter at least in many cases intimately connected with and derived from limestone; the black slates are not very fissile, but weather into irregular fragments. In the northwestern corner of the sheet there are a few isolated limestone masses. The one crossing the north fork of the American river is about 300 feet wide and about two miles long. Fossils indicating Carboniferous age have been found in the limestone masses southeast of Applegate's near the Central Pacific railroad, and also in the limestone mass exposed in the middle fork of the American river, two miles above Mammoth bar. In both places the characteristic forms are corals. This western belt of the Calaveras formation contains areas of fragmental volcanics and dikes and masses of basic igneous rocks, chiefly diabase and hornblende-porphyrites. The Calaveras formation east of the Mariposa beds consists of a succession of clay slate, sandstones and quartzites with lentils of limestone, and along the south fork of the Cosumnes river there is a good deal of mica-schist. The clay slate is, when fresh, very black and fissile, weathering into smooth fragments with sometimes almost a silvery luster. The basic igneous rocks, so abundant in the western belt, occur to a minor extent in the rocks of the Calaveras formation east of the Mariposa beds.

All of the limestone masses are more or less crystalline and fossils are very poorly preserved. In the limestone area, four miles southeast of Placerville, frequently occur crinoid stems which by their rounded forms indicate Paleozoic age.

The whole series up to the eastern margin has a steep easterly dip. Although differing in details the series is essentially similar in character throughout and might be described as the siliceous series. The strike of this siliceous series is north and northwest, except in the region southwest of Grizzly Flat, where the strike for a considerable distance is northeast. The change of strike appears to be due to the intrusion of the granodiorite.



SECTION OF MELTON MINE, EL DORADO CO.

Mariposa slates.—The Mariposa beds consist almost entirely of black slates not so much altered as those of the Calaveras formation. When fresh they are a deep black, but weathering changes them quickly to a light rusty brown. A little south of the Mile Hill toll-house in the northwest corner of the sheet appears a series of dark, partly volcanic sandstones and breccias, intercalated among the slates. This series continues up towards Colfax. It is well exposed along the canyon of the north fork of the American river, where it enters from the Colfax sheet adjoining at the north. The belt of the Mariposa slates contains numerous highly auriferous quartz veins. Ammonites and belemnites are found in these slates in El Dorado county. These fossils are similar to upper Jurassic forms of Europe. Another belt of Mariposa slates occurs in the lower foothills, extending southeast from Folsom. There are small patches belonging to this belt on the southwest corner of the sheet. The quartz veins in this western belt seldom contain gold in paying quantities.

IGNEOUS ROCKS.

Diabase and amphibolite-schist. — In the Carboniferous of the northwestern corner of the sheet are numerous dike-like masses of a fine grained dark green diabase usually partly or wholly uralitized (that is, with the pyroxene converted into hornblende).

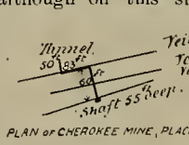
The amphibolites of the large area near the western margin of the sheet are dark green rocks, medium to fine grained, sometimes consisting almost entirely of amphibole, and are usually distinctly schistose with steep eastern dip. A part of them, especially north of Latrobe, are quite coarse grained. Although the larger part of them have been derived from diabase, it is not improbable that in many cases the original rock was gabbro. The two areas of light colored amphibole and talc rocks crossed by the road from Oleta to Bridgeport were probably pyroxenite originally. Some specimens contain pyroxene altering to tremolite and serpentine.

The long dike of diabase which follows the western contact between the western belt of the Calaveras formation and the Mariposa slates is quite variable in composition; the southern part, up to the granodiorite area of Coloma, is principally composed of a massive, dark green diabase-breccia; while to the north of this area of granodiorite it is roughly schistose and consists partly of massive dark green diabase and diabase-porphyrite with large white feldspar crystals, and partly of breccia of varying fineness made up of these rocks. The large area of amphibolite-schist north of Greenwood which is inclosed in the black Mesozoic slates is derived from diabase and diabase-porphyrite by dynamometamorphism, that is, metamorphism induced by intense pressure and movement. Near Greenwood there is altered diabase-porphyrite going over into normal amphibolite-schist. The Mesozoic slates contain a great number of similar smaller streaks and masses of amphibolitic rocks.

Gabbro-diorite.—West of Shingle Springs occurs an area of coarse grained gabbro, the pyroxene in which is partly converted into uralite; it is a compact and hard rock presenting great resistance to weathering. Large parts of this area are occupied by rough and rocky hills covered with grease wood (*Adenostoma*). Along the contacts with the amphibolite it is plain that the gabbro-diorite is the younger rock and intrusive in the former.

Serpentine, pyroxenite, peridotite, gabbro and garnet-pyroxene rock.—The Carboniferous slates north of Coloma contain several areas of serpentine in many places immediately mixed with amphibolite-schists. Smaller masses of pyroxenite and peridotite occur in them, and from these rocks the serpentine has probably been derived. The Coloma area of granodiorite cuts off the serpentine masses in the same manner as it has cut off the diabase dike near Placerville. South of that area the serpentine continues as lenticular and dike-shaped masses in the amphibolite with which it is intimately connected; so much so, indeed, that frequently it is difficult to outline the areas. East of Shingle Springs the serpentine contains small masses of a dark colored gabbro as well as a dike of quartz-porphyrite. A small mass of garnet-pyroxene rock occurs four miles southeast of Latrobe.

The large dike in the slates of the Calaveras formation entering the Placerville sheet near Volcanoville is in many respects interesting and complex. It is usually referred to as the "serpentine belt," and is continuous for about forty miles north of this sheet. The primary rock of this dike varies from gabbro or diorite to pyroxenite and peridotite, although on this sheet no considerable areas of either of the two latter rocks are present. Masses of serpentine and amphibolite-schist, often very difficult to separate from the gabbro, occur at frequent intervals along the belt. Both must be considered as alteration products of the rocks mentioned above. Near the mouth of Rock creek on the south fork of the American river the dike is cut off by granodiorite; south of that area it appears again somewhat narrower and principally composed of serpentine, although along with it occur small masses of peridotite and gabbro. The serpentine area that lies just southwest of Bridgeport may perhaps be considered as part of this serpentine belt.



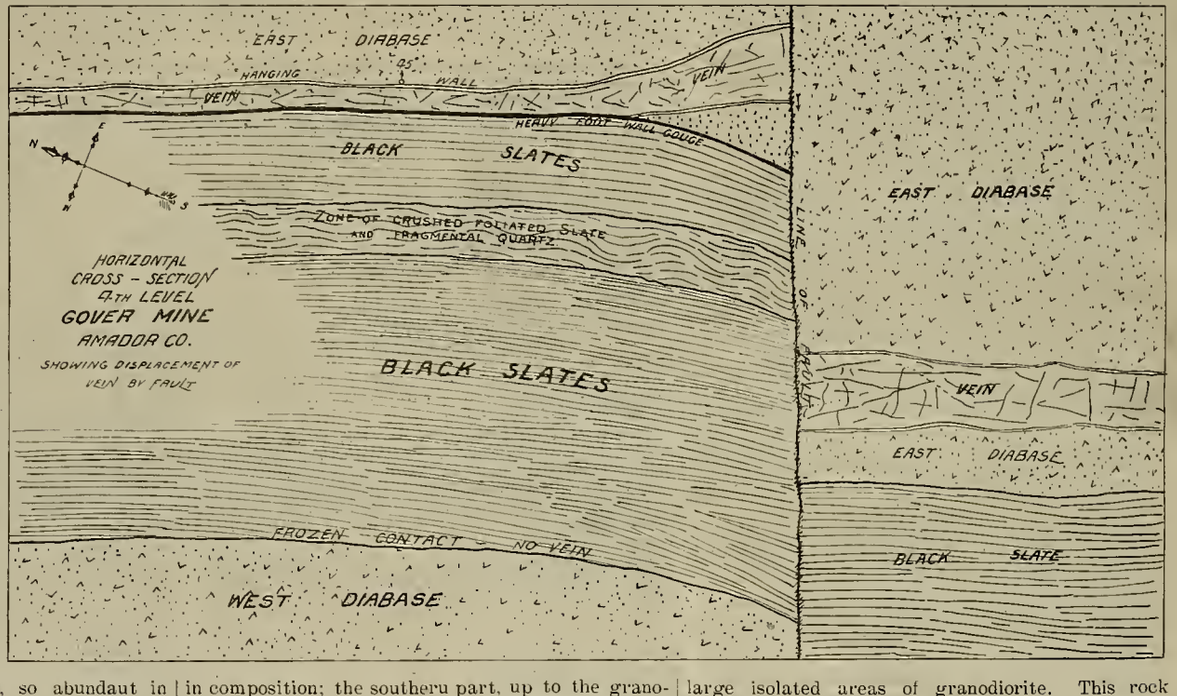
PLAN OF CHEROKEE MINE, PLACER CO.

Granodiorite, quartz-porphyrite and hornblende-porphyrite.—Intrusive in the slates of the Calaveras formation on the eastern part of the sheet are several large isolated areas of granodiorite. This rock usually metamorphoses the surrounding slates into micaceous and quartzite schists; the width of the contact zone varies from several hundred feet up to three-quarters of a mile, or in some cases even more; near Grizzly Flat the contact metamorphics frequently carry andalusite. At Grizzly Flat there are near the granodiorite contact small masses of a gabbroitic rock going over into granodiorite. The Coloma area of granodiorite is similar to the others in most respects, except that in some places the black mica is absent, and it has a tendency to grade into quartz-porphyrite. There is without doubt a gradual transition between the two rocks, as shown in the long projecting offshoots or apophyses at the southern end of the area.

PLAN OF FLAT RAVINE MINE, PLACER CO.

The quartz-porphyrite is a light-colored rock with porphyritic feldspars and quartz crystals in a groundmass of grayish or greenish color and of somewhat variable texture, though it is usually fine grained. The quartz-porphyrite, as well as the granodiorite, here contains much more sodium than potassium.

Closely connected with the granodiorite is the hornblende-porphyrite; it is a medium-grained rock with porphyritic feldspars and hornblendes in a groundmass of the same composition. It occurs at several places along the contacts, going over into



normal granodiorite; it also occurs as dikes and isolated massifs in the serpentines and other rocks in the vicinity. The hornblende-porphyrite massifs and dikes of Big Sugar Loaf and vicinity in places contain augite and grade into rocks of the diabase series containing no hornblende.

NEOCENE.

Auriferous gravels.—During the Neocene period the general topography of this sheet was that of a sloping table land, relieved by hills of moderate elevation. This area was drained by two river systems, one more or less closely corresponding to the forks of the present American river, and the other representing the branches of the Cosumnes. The gravels accumulated in them are now largely covered by volcanic material. The general direction of the Neocene drainage was as follows:

The old channel of the south fork of the American river enters the eastern margin of the sheet north of Pacific House and, crossing over, passes under the lava flow at Pacific House; from there it runs under the masses of Neocene andesite for about ten miles in a west-southwest direction down to a point between the two forks of Webber creek, northeast of Newtown; crossing the south fork of Webber creek it follows the present course of that creek for a considerable distance. The center of the old channel is here eroded, but there are numerous benches remaining to indicate its approximate course. In the vicinity of Placerville there is a complicated system of channels running south or southwest and tributary to the main fork. From a point between Placerville and Diamond Springs the channel was cut in a northwesterly direction, touching Granite Hill and entering the Sacramento sheet near Pilot Hill.

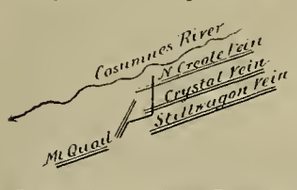
In Neocene time, the north fork of the American river followed a course which is now represented for a short distance by the divide north of Long canyon. The old channel again enters the sheet under the volcanic flow somewhere west of Todd valley and emerges from beneath the southern end of the volcanic area. Its course below this point is somewhat uncertain, but must have followed the present canyon of the middle fork pretty closely. Tributary to this former course are the Neocene channels north of Georgetown and between Volcanoville and Kentucky Flat. These tributaries flowed in a general north and northwest direction. In Neocene time, as now, the Georgetown divide formed a ridge between the two forks.

The course followed by the Cosumnes during the Neocene period is not perfectly known. It is certain, however, that one of the Neocene branches corresponding to the present Cosumnes headed near Grizzly Flat, and, flowing in a southwesterly direction across the present drainage, passed Henry diggings, Omo House and Indian diggings.

The auriferous gravels in this sheet consist of strata of quartzose and metamorphic gravel resting on the bedrock and usually overlain by finer sediments, such as clay and sand. The maximum thickness is not more than one hundred feet; usually it is much less.

The accumulation of auriferous gravels probably went on throughout the Tertiary, and may have begun even earlier.

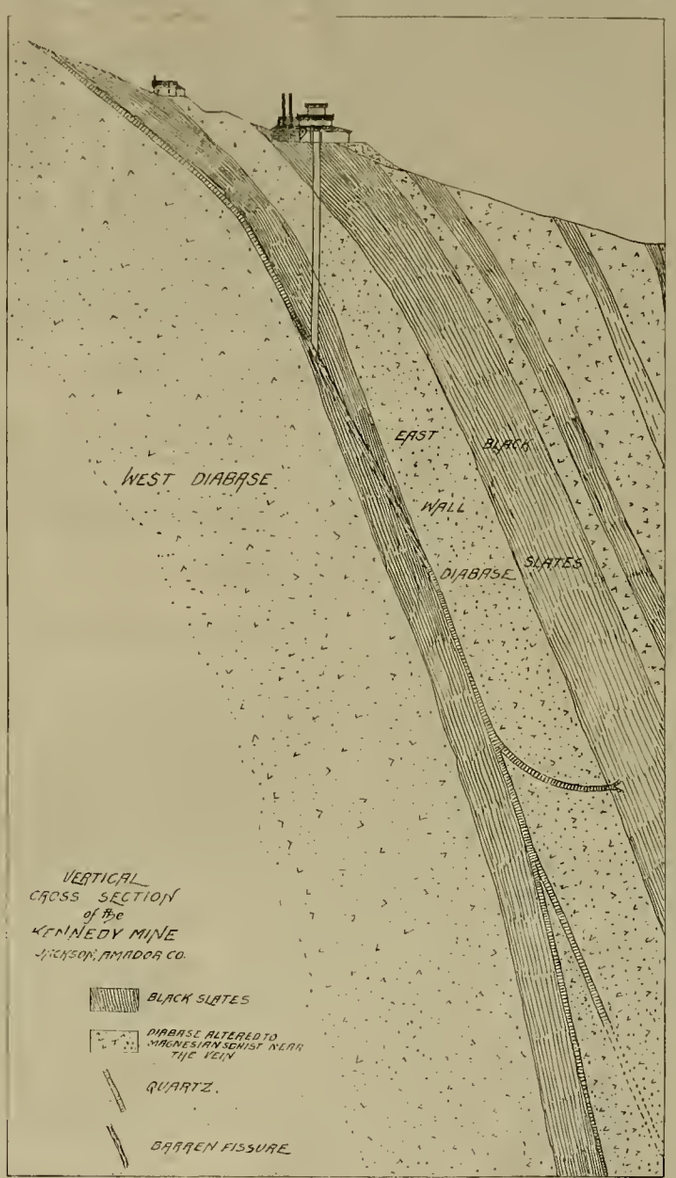
Rhyolitic beds.—The first volcanic flows which during the Neocene period came down from the slopes of the Sierra from the volcanoes uear the summit were rhyolitic iu character. The rhyolitic beds directly overlie the auriferous gravels and are composed of white or light-colored tuff usually fiue grained and occasionally containing scales of black mica. This volcanic fragmentary material doubtless came down in the form of many successive mud flows. Intercalated in the tuffs are beds of quartzose and metamorphic gravel and of light-colored clays and sands partly of volcanic origin. The gravels are usually somewhat auriferous. The total thickness of the rhyolitic beds is about 300 feet on the divide north of Long canyon and 400 feet in the vicinity of Newtown. Unlike the subsequent volcanic flows, the rhyolite did not spread over large areas, but only filled the valleys of the principal streams. During the interval between the rhyolitic and the subsequent andesitic eruption the former beds were considerably eroded and in places new channels were worn down to the bedrock. These, usually referred to as "cement channels," occur both north of the middle fork of the American river and in the vicinityof Placerville; in them the andesitic breccia ordinarily rests directly on shallow but rich gravel.



PLAN OF CRYSTAL MINE, ELDORADO CO.

Andesite.—The andesitic eruptions in the high Sierra flooded the larger part of the lower slopes with volcanic mud. Substantially the whole of the area of the Placerville sheet must have been thus covered, excepting the high bedrock ridges of the Slate mountains and, probably, the hills in the southwestern corner.

The andesitic beds, which are entirely fragmental in character, attain a maximum thickness of 700 feet on the divide north of Long canyon; in the vicinity of Placerville the thickness does not exceed 400 feet, while east of Placerville it again increases to 700. The lower part consists of heavy volcanic gravel, frequently somewhat auriferous, together with volcanic sands and tuffs; the upper part consists of a hard andesitic breccia and usually contains angular or subangular boulders of andesite often more than a foot in diameter. The andesite is dark gray to dark brown and contains porphyritic crystals of pyroxene and hornblende, the latter slightly prevailing; the cement uniting the boulders is light gray to light brown and consists of finely comminuted volcanic material. Nearly all of this rock has the rough and porous character which has been called asperitic.



PLEISTOCENE.

Earlier Pleistocene.—Along the rivers, and especially in the vicinity of Coloma, there are patches of gravel, from twenty to sixty feet above the present channel, which have been referred to the earlier Pleistocene. Along their upper courses below the limit of glaciation the canyons of the rivers usually are so narrow and steep that there is no room for these deposits.

Moraines resulting from Pleistocene glaciers are found in the extreme northeastern corner of the sheet. The morainal deposit here consists of a thin layer of angular fragments of granite and other rocks covering the surface of the Neocene volcauic flows, and partly the slopes of the canyons.

Alluvium.—There is but little alluvium on the Placerville sheet. Very shallow alluvial soil covers some of the valleys of the platcaus.

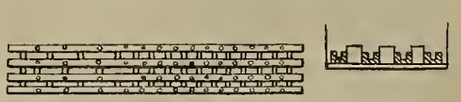
Gold-bearing gravels.—J. W. Marshall's discovery of gold in 1848 was made at Coloma, on this sheet. The alluvial accumulations of gold-bearing gravels in the preseut rivers and creeks were the first deposits worked. They were soon exhausted and the attention of the miners was turned to the gold in older deposits. A few bars along the American and Cosumnes rivers are still washed. The Pleistocene gravel benches along the present rivers have been and are now in part worked by sluicing and hydraulic mining. The hydraulic process is applied to the Tertiary auriferous gravels near Todd valley, on the divide north of Long cauyon, near Placerville and Newtown, aud at several places in the neighborhood of Georgetown, as well as at Mendon, Henry diggings and Indian diggings. The largest part of these gravels is, however, covered by volcanic flows, and is usually mined by drifting along the bedrock. Drift mines are at present worked in several places near Placerville, and also near Indian diggings.

Gold-quartz veins.—By far the most important mines on the Placerville sheet are located along the so-called mother lode in the area of the Mariposa slates, traversing the sheet from north to south. The mother lode, which must not be considered as a continuous vein, but rather as a belt of parallel though sometimes interrupted quartz-filled fissures, can be traced coutinuously as far north as the St. Lawrence mine on the Georgetown divide, and along it are found many celebrated mines, such as the Church Union, the Pacific and the Gopher-Boulder. The veins run parallel to the strike of the slates or cut them at a very acute augle. The dip is nearly always to the east and usually at a somewhat less steep augle than that of the surrounding slates. Along the veins of the mother lode frequently run narrow streaks of amphibolite-schist and serpentinc. The eastward bend in the strata caused by the intrusive granodiorite in the vicinity of Placerville is closely followed by the veins.

North of the St. Lawrence mine the mother lode is not well defined. The quartz veins are more frequently interrupted and are replaced by a peculiar kind of deposit, the seam diggings. In these a certain belt of slate is impregnated with minute irregular quartz veins, frequently very rich in gold. Such seam diggings occur at Georgia Slide, Spanish Dry Diggings, Greenwood, and other places. From the St. Lawrence one branch of auriferous quartz deposits runs up towards Georgetown aud Georgia Slide. Another belt begins by the Esperanza mine, north of the St. Lawrence, and continues with frequeut interruptions to the Sliger vein and Oregon bar, both on the middle fork of the American river. The quartz mines near Butcher ranch, and the seam diggings in Codfish canyon ou the north side of the north fork of the American river, may be cousidered as belonging to the same belt, but it is uot possible to trace the auriferous veins of the mother lode further.

On both sides of the great serpentine belt running from Volcanoville to the Cosumnes granodiorite area there are near the contact numerous small quartz veins, very rich in scattered bunches and pockets of gold. Few permanent mines are found, however, along these contacts.

The only important mining district in the eastern part of the sheet is that of Grizzly Flat. A long stretch of the contact of slates and granodiorite, from the middle fork of the Cosumnes to the "Buttes," is mineralized and accompanied by a great mauy auriferous quartz veins, the most prominent of which is that of the Mount Pleasant mine.



RIFFLE USED AT LINDEN MINE, ELDORADO CO.

Copper deposits.—Copper ores are found in very few places on the Placerville sheet, and nowhere in any considerable quantity. They occur as vein deposits aloug the grauodiorite in the zone of contact metamorphics, and one prospect lies south of Deer creek in the amphibolite-schist. Small masses of copper pyrites occur in serpeutine and amphibolite about two miles west of Greenwood.

Quicksilver deposits.—Quicksilver was formerly mined near Fanny creek, south of Big Sugar Loaf. Traces of cinnabar are said to occur near the mouth

of Hastings creek and in Clark's creek ravine one mile north from its mouth.

Chrome iron.—Deposits of chrome iron occur in California only in serpentine. On the sheet showing the economic geology two deposits are noted. Along the area described above as the "serpentine belt" many small pockets have been found.

Building-stones.—When massive, the granodiorite makes very good building-stone and is used in many places. Certain kinds of more massive rhyolitic tuffs, found at Smith's Flat and other places near Placerville, make a most excellent and easily dressed building-stone.

Black clay roofing slates are quarried at Chili bar, four miles north of Placerville, in the canyon of the south fork of the American river. There are at present several quarries, and the slate, which is of excellent quality, is used in many places in California. Good roofing slate could doubtless be obtained at other points in the Mariposa beds.

Militating against the development of the quarry industry is the lack of cheap transportation.

Personal.

CHAS. G. YALE, who has been seriously ill, is convalescent.

P. ROTHERMEL has returned from a visit to Shasta Co. mines in which he is interested.

P. R. ROBERTS has been appointed superintendent of the North Star mine, Nevada Co.

W. N. CROMWELL succeeds Jas. McNaught as counsel for the receivers of the N. P. R. R.

J. V. KEELEY, owner of the Clementina mine, Yellow Pine district, Santa Barbara Co., is in the city.

J. H. TIBBITS, a mining man of Amador Co., has gone to Arizona to take charge of a mine in Pinal Co.

FRED ZEITLER, superintendent of the Champion mine, has recovered from his recent illness, and is again at work.

W. B. MIDDLETON is examining mining property in the interest of Denver capitalists, in Robinsonville district, Baker Co., Oregon.

W. DE L. BENEDICT, a civil and mining engineer of New York City, and member of the American Institute of Mining Engineers, arrived here yesterday.

J. T. SMITH is inspecting Oroville mining properties in the interest of English capital. He has been examining some promising properties in the vicinity of Placerville during the week.

CAPT. WILLIAMS, for many years superintendent of the New Idria quicksilver mines in the southern part of San Benito Co., has resigned. Mr. E. G. Holmes is his successor as resident superintendent.

DR. R. BEVERLY COLE, of this city, has been honored by election to the Presidency of the American Medical Association, the first physician in this State to receive that distinction, since Dr. Logan of Sacramento was elected in 1870.

IRVING M. SCOTT delivered a lecture at Sacramento last Wednesday night under the auspices of the Capital City Lecture Association on "Great Guns and Armor Plates," which was heard with attention and interest by a large and appreciative audience.

W. H. TURNER, of Sutter Creek, goes to Johanneshurg, South Africa, next month, as mill man for one of the big mining companies on the Randt. His salary is to he $3,000 a year, transportation and living expenses. He was formerly superintendent of the Treadwell, Alaska, mine, and superintended mining operations for many years in Mexico.

G. H. ROBINSON, whose contract as manager of the Mammoth properties in Tintic, Utah, expired April 1st, is general manager of all the mining interests of J. R. DeLamar, with headquarters in Salt Lake. The interests under the control of Mr. Robinson include the DeLamar properties in Creede, Colo., the mine and mill in the Ferguson district, Nevada, the Golden Gate group in Mercur, Utah, and other concerns operating in Utah and Nevada under bond.

JOHN LEWIS KINGMAN has been appointed chief engineer of the Mexican Central, with headquarters at the City of Mexico. He was chief engineer of the Chihuahua division of the road during its construction, and was formerly chief engineer of the western division of the Atlantic & Pacific. He was assistant engineer of the Southern Pacific from July, 1868, to October, 1871; assistant engineer of the Kansas Pacific from October, 1871, to July, 1877, and assistant and locating engineer of the Atchison, Topeka & Santa Fe from July, 1877, to February, 1880. He was then with the Atlantic & Pacific until he was appointed chief engineer of the Chihuahua division of the Mexican Central in 1883.

COL. WILLIAM PRICE CRAIGHILL succeeds Gen. Casey as chief officer of the U. S. Corps of Civil Engineers. He was horn at Charlestown, Va., July 1, 1833. In 1849 he was appointed to West Point, and graduated second in a class of fifty-two members in 1853. During the war he received the brevets of Lieutenant-Colonel and Colonel for meritorious services. He was assistant professor of military and civil engineering at West Point for four years, from 1856 to 1859, and again, from 1866 to 1870, was on duty in the engineer hureau. He has been sent to Europe twice on engineering missions, and has visited this coast five or six times. He is familiar with the wants of the country in military fortification, harhor improvements and other general engineering projects. It was supposed Col. Mendell would he tendered the position, hut as he will be entitled to retirement on Octoher 1 the President appointed Col. Price.

W. C. RALSTON, the Secretary of the California Miners' Association, returned this week from a six months' sojourn in London and Paris, where he was a witness of the present extraordiuary activity in South African mining shares in those cities. He says that the published accounts of the craze are not exaggerations; that more zeal than judgment is disolayed in the investment of millions of pounds sterling, and that, indirectly, the inevitahle collapse will make it easier to direct the attention of the English seeker after legitimate miniug investments to the superior permanent nature of our California gold properties. Upon his arrival at New York he was interviewed by the New York *Herald* on the subject of mineral lands, which, in the issue of April 28th, gave a two-column illustrated statement of the facts in the case wherein the commonwealth of California, through its miners, is resisting corporation efforts to ahsorh large areas of the public domain. In compliance with telegraphed suggestions from this oity, he went to Washington, where he put the case fairly and squarely before every one at the seat of tbe federal Government by extended interviews, published in Washington's leading journal.

Coast Industrial Notes.

—The British patrol fleet will be shortly withdrawn from Bering sea.

—Judging from the present demand, a California bicycle factory should pay well.

—At Chino there has already heen planted this season nearly 4000 acres to sugar beets.

—The Western Sugar Refinery has advanced the price of granulated sugar one-eighth of a cent three times within a week.

—Woodbury concentrators are heing sent to Idaho and Utah. Hendrie & Bolthoff of Denver are the Colorado agents.

—According to the Phœnix *Gazette*, the Southern Pacific Railroad is about to commence work on its Mesa City extension.

—Up to date 4000 carloads of oranges have heen shipped East from southern California and about 1300 carloads still remain on the trees.

—A large spur wheel, weighing 6300 pounds, was cast at the Miners' Foundry, Nevada City, this week, for the Federal Loan Mining Company.

—A Phœnix, Arizona, manufacturer makes affidavit to the fact that, on an importation of rosin tbat had cost him $160 in the East, he paid $720 freight.

—The old hoilers of the steamship Columbia, which have heen replaced hy new ones at the Union Iron Works, are being broken into scrap iron, worth $3.50 a ton.

—Orders were recently received from Moscow, Russia, and Warsaw, Poland, for a earload of Sierra Nevada redwood, to he used in the manufacture of lead pencils.

—The San Francisco Gaslight Co. has cut the price from $2.00 to $1.75 per M. feet. A reduction is also announced for gas used in gas engines and for manufacturing purposes.

—The Stanislaus and San Joaquin Canal Co. are building a ditch forty-seven feet wide from Knight's Ferry to Lathrop—50 miles. Nearly 300 men are working day and night on the job.

—The Northern Pacific railroad has prepared a revised schedule of wages, which will soon go into effect. It embraces the entire system and adjusts inequalities of former reductions.

—The Southern Pacific Co.'s net earnings for '94 were $16,050,949: for '93 the net earnings were $18,158,790. The total earnings for the year above all fixed charges and liabilities were $2,139,184.

—Portland, Or., is going to try the experiment of canning horse flesh. Horse meat as an article of food is not new to the people of Oregon. The old missionaries from 1833 to 1844 used it as a regular diet.

—Tbe Spring Valley Water Company are now building a tunnel from the Colma district about Lake Merced to the Pacific ocean to carry off all drainage water and keep the lake pure. It will cost $150,000.

—The prohibition of machinery from China may end by the results of the Japanese war, and American manufactures have a new market—a probability of immense importanee to the industrial interests of this coast.

—A new oil well at Puente produces sixty barrels daily. Another one recently put down yields fifty barrels, while from the largest well 120 barrels are pumped daily. Thirty wells are now operated aud others are heing bored.

—The Fresno owners of the new water and electric power plant heing put in on the San Joaquin river have offered to furnish power for machine shops of the S. F. and S. J. Valley Road if built there at one-half the price of steam power.

—L. B. Frazier, near Ukiah, is experimenting with a project which, if successful, means much to Mendocino county. He has huilt a kiln and proposes to make tar, turpentine and by-products from the unlimited pine forests of that region.

—Some experienced paper mill men, who have heen connected with the Oregon City, Or., mills, propose putting in a $150,000 plant at Green Basin, on the eastern division of the Oregon Pacific railroad, to make wood pulp from hemlock timber, which is abundant there.

—The Arizona Marble Company, whose deposits of marble lie across the Cochise county line, in Pima county, have sold to a syndicate of Colorado capitalists 500 carloads of marble to be delivered as fast as practicahle. This marble is to he used for building purposes, floors, etc., in Colorado's finest buildings.

—During the flood of 1894 ahout twenty-three fishwheels were washed out in the Columhia near The Dalles, Oregon, at a loss of $80,000 to the owners. When the season opened on the 10th of last month every wheel had been replaced. Last season there was a phenomenal run of salmon. This year it is not expected to he so large.

—Besides the deplorahle fatality, seventeen men having perished, the loss of the schooner C. G. White has heen a hlow to the furriers. After much difficulty Leihes & Co. obtained permission to hunt otters in Bering sea, which was prohihited hy this Government for several years. The White had on board fifty otter skins valued at $20,000.

—California imports condensed milk by the trainload. A large share of this product is used hy California farmers. There is no country in the world where milk can he produced so ahundantly, cheaply or continuously as here, hut we keep right along huying condensed milk, and the pile of empty cans back of the farmers' houses keeps getting larger.

—The right of way for the 56 miles of proposed railway hetween Astoria and Goble, Or., along the south bank of the Columbia river, has heen secured. There will be three tunnels on the road, one of 200 feet in length and one helow Ranier of 175 feet. Work can he pushed at hoth ends of the tunnel, and it can he completed in eight or ten months.

—It is now thought that the sale of $196,000 worth of Los Angeles refunding honds to Street, Wykes & Co. of New York for a premium of $20,000 may have to he canceled on account of a law which went into effect on March 27th, providing that in the case of refunding bonds the original holders of the bonds shall have the first opportunity to purchase them.

—L. Grothwell of this city proposes to run an electric road from Napa north to Calistoga, twenty-seven miles. He also proposes to huild to Napa Soda Springs and the asylum and cover Napa with electric lines. He estimates the cost of the proposed work at $400,000. The road to Calistoga would parallel the Southern Pacific Company's road the entire distance.

—The Golden State and Miners' Iron Works, of this city, have an order from Harris & Witter for a mammoth clamshell dredger for the isthmus; the hull is to he 50x100 feet, 10 feet depth of hold; the engines tandem compound condensing, spuds seventy feet long and twenty-five inches diameter, the bucket to hold four yards and he operated hy 1¼-in. steel cable. An electric plant will furnish light, and the entire outfit will cost $36,000.

—There has been submitted to the Mexican Congress for approval a contract between the Mexican Government and Samuel Brothers, of the City of Mexico, for the supply of $2,000,000 worth of rolling stock, bridges, and machinery for shops, etc., for the Tehuantepec railway; dredges, tugs and lighters for the harhors, and steamships for lighthouse purposes. Samuel Brothers are also negotiating for the construction of the harbors of Coatzacoalcos and Salina Cruiz, on the Atlantic and Pacific extremities of the Tehuantepec road.

—Seattle, Wash., has given a $500,000 subsidy to the Seattle and Lake Washington Waterway Company to fill in the tide flats and excavate a ship canal to Lake Washington. Work will hegin on the 23rd. It includes excavation of two waterways, connecting the Duwamish river with the souud, the excavation of a canal from the harhor to Lake Washington, a distance of two miles, and the filling of ahout 1500 acres of tide lands. It will cost ahout $7,000,000 aud occupy about five years; the money will be furnished by St. Louis parties, represented by the Mississippi Valley Trust Company.

—Two extensions of the Washington & Columbia River Railroad are contemplated. One plan is to build from Daytou, Wash., to Grain City on Smoke river, tapping a productive country. Another plan is to construct a new line from Pendleton, Or., to Camas Prairie and the John Day region, involving eventually construction through to California, coming into this State at the head of the Sacramento valley, with San Francisco as the objective point. The latter line will run through Umatilla, Grant, Harney and Lake counties in Oregon and enter this State at the northern horder of Modoc county.

—The iron ship May Flint is due next month with 5000 tons of coal from Baltimore. She spreads 10,000 square yards of canvas and is the largest sailing vessel afloat. She has four steel masts, and from the keel to the topmost point of each mast is 184 feet. The masts from deck to truck measure 159 feet. The fore, main and crossjack yards are each 93 feet, the howspirt and jihhoom 40 feet, and spanker hoom 56 feet. The masts are hollow and 30 inches across at the deck. The ship will carry 30 sails, or enough canvas to make an awning a mile square. The few sailing vessels that approach the May Flint in size are the French five-masted steel hark France, 3624 tons; the British four-mast ship Liverpool, 3330 tons, and the American four-masted ships Roanoke and Shenandoah, 3400 and 3258 tons respectively. The May Flint is 3923 tons.

—The most important results of the Japanese-Chinese war that has just ended will he found not in the money indemnity that China will pay nor the territory it will cede to its victorious antagonist. These results will come in the industrial revolution which China will receive from its conqueror. In this China will gain far more than it has lost, while the Japanese as leaders in the new civilization will achieve greater triumphs than any which war affords. The opening of the Chinese Empire to the arts and industries of a higher civilization is an event of interest and importance to California and the Pacific coast. The manufacturing nations of Europe, especially England, will look on this movement with little favor; but it is wholly heyond their power to prevent it. The first result will he an enlarged demand for lumber, the next a market opened for mining, milling, manufacturing and agricultural machinery.

—Mr. T. G. Cantrell of the National Iron Works, heing recently asked for his opinion as to how hest add to the State's population, said: "Causes must he created to produce a desired effect. The natural tendency of people is to go where they can find remuneration for their labor. In the early history of the State, gold mining was the primary cause for inducing immigration. The same industry to-day, if pursued legitimately, would draw more people to the State, and, through the demand for necessary machinery, supplies, etc., create renewed activity in Sau Francisco's husiness community, and in consequence invite new-comers. The world suffers from overproduction in everything but gold, and California possesses the precious metal in greater quantities and with more advantageous facilities for its extraction than any other part of the country. Let it he known that capital takes no greater risk in mining than in other enterprises, with promise of a hetter profit than can he realized from any other investment at the present time. Encourage an industry that invites seekers after wealth, and people will flock here instead of going to Africa, Australia or Alaska. By a revival of the legitimate mining interest, there will he no more trouble in getting 500,000 people in San Francisco than when it was discovered that gold was to he found here forty years ago."

Obituary.

J. H. SEELLY, president of Amherst College, died there last Sunday in the 71st year of his age.

H. H. COTTON, an old and well-known miner, was instantly killed last Thursday hy a cave in the Malakoff mine near North Bloomfield, Nevada county.

SUPERINTENDENT J. F. LEMON, of the New Carmine mine in the State of Chihuahua, Mexico, and two other Americans, were killed recently hy Mexicans. The cause of the murder is as yet unknown.

DR. JAY GUY LEWIS, a well known mining man, died at his home in Sparta, Oregon, last Sunday, after a brief illness, of erysipelas. Dr. Lewis was superintendent of Oregon's exhibit at the World's Fair.

FRANKLIN FAIRBANKS died at his home in St. Johusbury, Vt., April 24, 1895, in his 67th year. He was the youngest of four sons of Erastus Fairhanks, Governor of Vermont, and founder of the famous scale works to which he gave his name. He lived all his life and died in his native town.

ECKLEY B. COXE died at Hazleton, Pa., last Monday, aged 65 years. He graduated at the University of Pennsylvania in 1858. After six months in the anthracite coal region of Pennsylvania, he engaged in topographical geology, and went ahroad in 1860. Two years were passed at the Ecole des Mines in Paris, and a year in the Freiberg mining school, after which he continued for nearly two years studying the mines in England and continental Europe. As an expert on the mining and preparation of anthracite coal, and on the subject of mine surveying, Mr. Coxe frequently lectured before scientific hodies. He was prominent in the American Institute of Mining Engineers, heing its president from May, 1878, until February, 1880; also, in the Institute of Mechanical Engineers, of which he was vice-president from April, 1880, until November, 1881; and he was a memher of the American Society of Civil Engineers. He published papers on technical subjects, chiefly in the transactions of the societies of which he was a memher, and translated the first volume of the fourth edition of Weishhach's "Mechanics of Engineering and Construction of Machines." From 1880 until 1884 he was a State Senator in Pennsylvania.

J. L. STEWART, of Philadelphia, is here and talks of building fifteen gas works in as many different coast cities. He thinks the charges in San Francisco for gas are unnecessarily high; the two gas companies charge $2 a thousand feet. He says he can furnish it for $1 a thousand and then make money. He estimates that the new plant here, with the mains requisite, will cost $3,000,000. With gas at $1 a thousand feet it would be as cheap as coal at $7 a ton.

Notes on Recent Compressed Air Plants.

To the Editor.—The Fulton Engineering and Ship-Building Works of this city are at present extensively occupied in the manufacture of specially high-class compressed air plants for different enterprises in this State.

It is now less than a year since this company began to make air transmission one of their specialties, and yet they have in the course of construction the three most distinctive compressed air plants ever put in the State, besides a number of smaller ones which are not specially interesting in their nature.

The largest plant, viz., the 700-horse power plant to operate the pneumatic guns at the Presidio, has already been touched upon in a former communication. This plant is nearly finished and in the course of the next thirty days will be tested. In appearance it even exceeds the anticipations of its designers, and scientific results are expected from this test.

The most interesting plant to miners in this State is that for the North Star Mining Co., of Grass Valley. This company proposes to inaugurate 800-horse power for the operation of the various engines and motors connected with the mines in their charge. The first plant of 250-horse power is now under course of construction by the Fulton Company.

The North Star Company, during the last six months, have been investigating the comparative methods of electrical and compressed air transmission, and for their work have decided in favor of the latter. A steel pipe, of twenty inches in diameter and something over a mile long, conveys the power water, under a pressure of 775 feet, down to Wolf creek in the town of Grass Valley. Directly on the creek will be erected a stone power-house and distributing manifolds for the three plants, the first of which is at present being installed.

About 125 feet vertically above the power-house, and 1500 feet distant, will be located the hoisting works and machinery first to be operated by this plant.

In the design and construction of this plant it has been the endeavor to make it the most economical water power compressed air plant ever made. The type of the water wheel has not yet been selected, but it will be either the Knight or the Pelton wheel, depending upon some tests which are now being made. The wheel will be placed directly upon the shaft, and be about nineteen feet in diameter.

The compressors will be of the duplex Rix tandem compound type, having submerged copper intercoolers of large extent. The cylinders of these compressors will be so connected that any cylinder or half of any cylinder can be operated independently of the whole system. The water wheel will make 110 revolutions, and the regulating devices will be such as to maintain this speed and to operate the wheel at one-fourth, one-half, three-fourths and full gate economically.

The air will be conducted from the compressor to the mine in a large main and will there pass through a reheater of peculiar and special design. In this reheater the air will be heated to between 200° and 300° F., increasing its volume about 35%; and thence directly to the hoisting engines, and through carefully insulated pipes to pumping engines some three or four hundred feet below the surface.

In comparing this plant with electrical transmission, it is expected that the economy will be vastly superior. There is no doubt that in comparing these two modes of transmission, for short distances, electricity is vastly inferior in economy, and for the following reasons: The water wheel will of course give the same efficiency in either case; the dynamo will give an efficiency not to exceed that of a compound compressor built in the style of the Rix compressors. Allowing for short distances, the electrical transmission on the wire will suffer no more loss than compressed air in a good-sized pipe; thus one can see that the same power will arrive at the motors in either case. At this point there is no means of increasing the quantity or the pressure of the electrical force and it must go to its motor as it stands, while with compressed air, at an expenditure of not more than one-quarter of a pound of coke per horse power per hour, which is insignificant, the volume may be increased 35% and used at once in the motors. This places the net efficiency far higher than can be expected in electrical transmission.

This is the first reheating plant placed in a mine in this State, and possibly of this nature in the United States. The principle of the system is that employed in the large power transmissions of Paris and of Birmingham, Eng., and which have demonstrated that compressed air power is the cheapest yet served from any power station that has to purchase its fuel for prime movers.

There is little doubt that the result of some experiments now being conducted under my supervision will show that air motors may be constructed in such a manner and of such material that air reheated to 500° may be successfully used. If this is the case the transmission losses would be done away with, and the original prime mover power can be used at the motors. In the use of compressed air in mines there need be no changes of any consequence in the ordinary steam motors and pumps, and therefore it entails a less expense in changes and alterations in its installment; and besides, the exhaust from an air motor is not offensive—in fact, it assists in purifying the air underground.

I think in the near future the advantages of compressed air transmission will be more generally acknowledged than at present, and that there is abundant opportunity in this State for its economical use.

The Fulton Company are also building a large compressed air plant for the Golden Cross Mining Company, consisting of eighteen-inch Rix compressors driven by condensing Corliss engines. This will make an economical plant, and all mines which have any regard for their wood pile should operate their compressed air machinery by economical engines. When this plant is in operation data will be furnished to the public, giving the amount of wood consumed per twenty-four hours for operating the rock drills driven by this plant, so that mine owners can make a comparison with the plants which they are now operating. Corliss engines now are very little more expensive than slide-valve engines and in running, condensing like this plant, the fuel bill will be at least 40% less. In a large plant this will pay for the difference of cost in a very short time.

The Fulton Company, as stated before, are making a specialty of this subject of compressed air transmission, and are guaranteeing economic results. Any one desiring information in the matter will receive full data upon addressing the company a communication. It is entirely probable that any ordinary compressed air transmission can be installed at no greater expense than an electrical one and with better economic results.

E. A. Rix.

San Francisco, May 15th, 1895.

The Genesis of Ore Deposits.

One of the most notable recent contributions to the science of economic geology, viewed from the theoretical standpoint, says the *Engineering Magazine*, is the criticism by Prof. Joseph Le Conte (offered at the Bridgeport meeting of the American Institute of Mining Engineers) on Bergrath F. Posepny's great essay on the genesis of ore deposits. This latter has elicited much interesting and some useful discussion. After doing justice to the high merits of Posepny's treatise, Prof. Le Coute "cannot but think that he (Posepny) carries his ascension views much too far; that, in his zeal against the extreme lateral-secretion views of Sandberger, he has gone to the other extreme of ascensionism, and that a truer view of either may be found in one that shall combine and reconcile these two extremes." It will be remembered that Posepny draws a sharp distinction between the superficial and the deep circulation of underground waters; the water in the former case containing air, and therefore oxidiziug; the water in the other case being destitute of air, and therefore non-oxidizing; the one circulation being driven by gravity alone, the direction of current being determined by the plane of outflow; the other being driven largely by heat received in the lower parts of its circuits, and the direction of its current being mainly upward—from which view it follows that metallic sulphides are not deposited from the waters of the "vadose" (superficial) circulation, unless under the exceptional conditions of the presence of excess of organic matter; and therefore that the presence of metals in the form of sulphides is usually a sign of deposit from ascending waters of the deeper non-oxidizing circulation. Posepny has also introduced, as a substitute for the indefinite "unknown depths" of other geologists, the term "barysphere" to define a region in the interior of the earth, the materials of which are heavier, because more metalliferous, than the superficial "lithosphere" visible to us. This "barysphere" would therefore be the source of ore deposits, and not the higher rocks; but Sandberger and his followers have demonstrated by defined analyses that these upper rocks, especially in their heavier basic mineral constituents, contain the metals in sufficient quantity to form ore deposits by leaching, concentration and precipitation.

Prof. Le Conte, inquiring whether there is a "barysphere" within reach of circulating water, admits (as all do) that there must be such a region somewhere, but doubts whether it is near enough to the surface. The mean density of the earth as a whole being about 5.5, while that of the surface rocks is about 2.5, he argues that, assuming the simplest rate of increase—a uniform one—the central density would be 14.5, and an actual density equal to the mean density would be found at a depth of 1000 miles. At a depth of 100 miles, therefore, the increase would be 0.3 and the density only 2.8; but that is only about the density of the more basic eruptives. But Prof. Le Conte does not believe it probable that circulating water ever comes up from any such depth. It may come, he thinks, from as deep as ten miles, where the increase over the superficial density would be wholly inappreciable. If the rate of increase is not uniform, on either explanation of the high mean density of the earth, whether (1) by condensation by increasing pressure or (2) arrangements of materials of a primal fused earth according to their relative specific gravities—the probability being in favor of both causes—at all events the increase must be progressive toward the center, and he thinks it hard to conceive the conditions under which a dense metalliferous shell a little way beneath the surface could be formed. From a chain of reasoning which cannot be followed here he concludes that below a certain moderate depth—say eight or ten miles—there is no true circulation. Below this the compactness of the rocks from increasing pressure would inhibit further penetration, while capillarity, which strongly impels movement in dry, porous materials, also acts as strongly to retard it, once the rocks become saturated.

Prof. Le Conte believes that a more comprehensive theory than the ascension or the lateral-secretion theories is needed, and that, in the uncolored light of a broader view, many of the difficulties and obscurities of the subject disappear. His general conclusions are:

"1. Ore deposits, using the term in its widest sense, may take place from many kinds of waters, but especially from alkaline solutions, for these are the natural solvents of metallic sulphides, and metallic sulphides are usually the original form of such deposits.

"2. They may take place from waters at any temperature and pressure, but mainly from those at high temperature and under heavy pressure, because, on account of their great solvent power, such waters are heavily freighted with metals.

"3. The depositing waters may be moving in any direction—up-coming, horizontally moving, or even sometimes down-going, but mainly up-coming, because by losing heat and pressure at every step such waters are sure to deposit abundantly." [This has been used by some as an argument that mines, as a general rule, increase in richness with depth—a state of things not substantiated by experience.]

"4. Deposits may take place in any kind of waterways—in open fissures, in incipient fissures, joints, cracks, and even in porous sandstone, but especially in great open fissures, because these are the main highways of ascending waters from the greatest depths.

"5. Deposits may be found in many regions and in many kinds of rocks, but mainly in mountain regions and in metamorphic and igneous rocks, because the thermosphere is nearer the surface, and ready access thereto through great fissures is found mostly in these regions and in these rocks."

The Oro Blanco Country.

Written by Don C. Pickett, Ex-Superintendent of the Quijotoa Mines.

The Oro Blanco range commences about sixty-five miles south of Tucson, Arizona, takes a southeasterly course through the southern part of Pima county and enters Sonora, Mexico, about nine miles south of the little town of Oro Blanco.

The altitude of the Oro Blanco country varies from 3000 to 4500 feet above sea level.

The general formation in and about the locality is porphyry, with some granite scattered throughout the hills and canyons. The Oro Blanco mining claim consists of a full sized claim, being 600 feet in width by 1500 in length. The strike of the vein is a little north of west and south of east.

As I followed the ledge over the surface, I found many traces of work done years ago, no doubt by Mexicans or Spaniards; and at one place, immediately west of the shaft, the entire vein had been taken out for the length of 150 feet, and to a depth of at least thirty feet. This work had been many years ago, and from the fact that I could find but very little traces of a "dump" on or about the mine, I could only conclude that the ore taken out had been worked to almost the last pound in the crude way peculiar to those early miners.

From inquiry made in regard to this work, I was reliably informed that at one time, some thirty-five years ago, there were forty-seven arrastras at work on this ground, and over 150 people lived on the proceeds taken from this ledge. In evidence of this, I looked for and found many traces of arrastras in the canyon and flat immediately below the work. That the ore taken out from this long deep cut paid well in gold is beyond question, else a whole community could not have existed upon the proceeds by their slow and crude methods. From the fact that no waste dump could be found in or about the canyon and flat where the arrastras had been located, or at the mine, it would appear that nearly every pound had been worked in some manner. The cut is filled to some depth by debris and wash from the hillside, carried down by the action of rain and storms, but the walls of the ledge stand firm and can be distinctly seen throughout the entire length of the excavation. I would say that at least 1500 tons of ore have been taken from this cut and other excavations along the ledge.

That the mine should have been abandoned by the Mexican owners of that time was something of a mystery to me, and I endeavored to find out the reason for its abandonment. From John Bartlett and R. N. Leatherwood I learned that in the early "sixties" about forty families lived in the canyon, and virtually gained their living by the gold produced from the Oro Blanco mine. Few white men lived in the country at the time, but the few who did live here concluded that if the mine was good

for the Mexicans it was good for them, so a number of them banded together and ran the Mexicans out, giving as a reason that they, the Mexicans, not being citizens of the United States, could not own and work mining claims within the limits of the United States.

The mine was then located and claimed by the head instigators of the outrage. While the arrastra process was sufficient to satisfy the slow-going Mexicans, it failed to satisfy the more ambitious Americans. A ton per week to the arrastra, together with the fact that while one man worked with the pick and shovel two must stand guard to protect the ore from Indians and wandering bands of criminal Mexicans, soon convinced them that they had acquired something they could not utilize, hence the mine was abandoned. It lay unclaimed for a number of years, and time, storms and Indians obliterated nearly every trace and habitation of the people that once lived and prospered on the proceeds of the mine.

In later years silver mining took up the time and attention of most of the miners of this country, and gold ores of $15 to $20 per ton were passed over by miners in their quest for high-grade silver ores. It is only in the past eighteen months that the demand for gold properties has sent the prospectors seeking the yellow metal in this quarter, and among the first claims taken up and located in this district was the old Oro Blanco. Since that time a new shaft has been sunk and the property slowly developed, and under modern machinery and management it bids fair to become a valuable property.

About fifty feet from the easterly end of the cut, and yet further east than the shaft sunk by the present owners, a shaft was put down during the early part of last year, and twenty tons of the ore milled at the Yellow Jacket mill as a test of its value and to pay expenses of the work. The superintendent of the Yellow Jacket mill informed me that the ore gave an average of $20.50 per ton in gold. The shaft is sunk on the vein, and goes down almost vertical, the ledge having hardly any "dip" or incline. The walls are porphyry, smooth and well defined, with a clay gouge from one to three inches thick on each wall. The vein is from five to six feet in width between walls; the vein matter is composed of soft decomposed porphyry and ground up, granulated quartz, thoroughly disseminated through it, most all of which is stained with oxidized iron. The soft, ground-up condition of the vein shows immense action at some time or other. The gold extracted from this ore is of a character known as fine "shot gold," being heavy and remarkably pure, notwithstanding the fact that the name "Oro Blanco" signifies "white gold."

From seven samples, taken from the ends and bottom of the shaft, returns were made of an average of $13.50 gold and 2.60 ounces silver per ton.

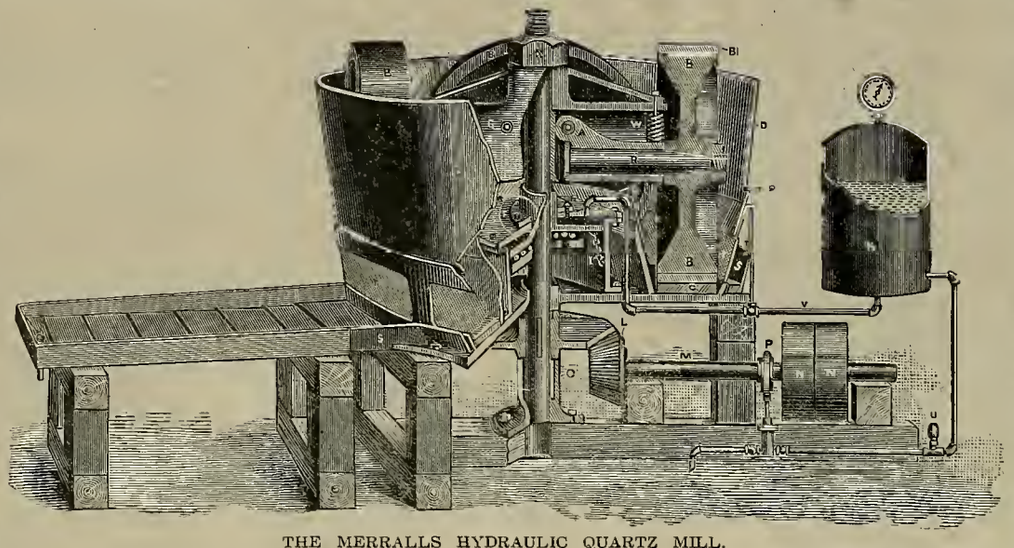
Labor can be procured at from $1.50 to $3 per day for miners and from $1 to $1.50 for common laborers.

First-class roads from Tucson, a distance of about eighty miles, and a new wagon-road over the mountains to Nogales, a distance of thirty-two miles, give cheap freights and good service. The climate and water of the Oro Blanco mountains cannot be surpassed in any mining camp in the United States.

The Merralls Mill.

The Merralls Hydraulic Quartz Mill is the latest applicant for favor in the eyes of the miner for pulverization of ore. The claim of the owner and inventor that this mill is based on common-sense ideas, and is superior to any other wet mill now in existence, is to be determined by practical test.

"As shown in the accompanying illustration, the



THE MERRALLS HYDRAULIC QUARTZ MILL.

cast-iron bottom of mill rests on heavy trestles, on which are cast the annular mortar, and in which rests the steel die, *C*.

"*S* shows the chute for carrying off the pulverized ore and water as it comes through the screens, *T*, and is conveyed to the amalgamated plates, as shown. *T* are the screens, the entire circumference of the mill, which gives this mill very large screen area. Consequently the ore is not slimed, for, as soon as pulverized, it passes out of the mill into the chute, *S*. *B*, *B* are the crushing wheels, made open, as shown, to facilitate the discharge of the crushed pulp through the screens. *B1* shows the steel tire or shoe around the wheels, *B*, *B*, made very massive and strong. At *I* is shown the cylinder, bolted to the pan, in which is the piston, *H*, with part of the piston extending up the upright shaft. At *L* is shown a collar securely fastened to the shaft, and between the collar and piston, *H*, is a ball-bearing. These are steel balls running in oil to reduce the friction that occurs when the pressure of water is applied to the piston, *H*. This piston has a leather cap (common to all hydraulic valves) fixed on it, and does not revolve, being held by the chains, but the upright shaft revolves through it. *F* is the top of the cylinder, bolted to the cylinder. *E* shows the inside cone of the annular mortar around which the crushing wheels revolve. At *P* is shown the pumps on the horizontal shaft, *M*. *K* shows the tank or receiver for the water that is pumped by the pump, *P*. In this tank is a column of air which acts as a spring to drive out the water when the three way cock, *O*, is opened. *U* is a relief valve, that can be set at any desired pressure, and regulates the amount of pressure on the piston, *H*, and in the tank, *K*. At *A* is shown the hinged box in which the wheel shaft, *R*, revolves, and on which are keyed the crushing wheels, *B*. *W* shows the massive coil springs, in nests, that receive the pressure that is imparted by the action of the water on the piston, *H*, through the spider, as shown; and when the pressure is on, the steel springs, *W*, close within three inches, so that in case a bolt, nut, drill or hammer should get into the mill, each wheel will lift up and pass over the obstruction. Each wheel acts independent of the other one, and is hinged by the hinge bolt, *G*. At *V* are shown the water pipes from tank to piston; *L*, the gears; *D*, splash apron. *N*, *N* show tight and loose pulleys. At *O* is shown the step-box that holds the upright shaft in position. *X* shows the tension nut, on the top of the upright shaft, to regulate the height of the spider.

"Ore is fed into the mill from the self-feeder, or by hand, through the ore chute; and as the crushing wheels revolve, it is thrown under them and soon reduced. The scrapers (not shown) keep the ore on the die. As soon as reduced fine enough, it passes out of the screens, consequently is not slimed, but in a good condition for concentrating. By turning the three-way cock, any desired pressure can be brought on the crushing wheels—10, 15, 20, 25 or even 50 tons pressure on each wheel—and this instantly and with no dead weight to be carried around, as the ball-bearing under the piston and between the collar on the shaft reduces the large amount of friction that might exist. It has at the same time a twisting motion, on the same principle as one standing with a walnut under his heel, his whole weight resting on it, and it does not crack; but the moment one twist is given by the foot, the entire molecular structure of the shell is broken. So with the manner of reducing ores in this mill, which is going on continually. As fast as it is fed into the mill, it is under the crushing wheels, reduced, and out over the amalgamated plates, ready for amalgamation. Having been ground by the twisting motion of the wheels, the gold is brightened and the rust or film removed, hence a large saving here takes place which will pay for a mill in a short time, by reason of this scouring of the gold."

W. A. Merralls is the inventor and owner of this mill. His address is Room 12, 3rd floor, Mills Building, San Francisco.

HOW COAL IS HANDLED HERE—READY FOR THE RETAILER.

PART OF A YARD.—*See page 305.*

We hear of finds in other parts of the State, and of course, all are "rich." The orchardist and gardener put the big peaches and strawberries on top in the box; so the miner, being human, does not hide his nuggets at the bottom of the ore-sack.

When a belt gets saturated with waste oil, an application of ground chalk will soon absorb the oil and make the belt workable.

Scientific Progress.

A Changing Map of Trade.

The *Age of Steel* says: "There is no fixedness in commercial supremacy. It has come and gone from one nation to another, and all the way down the page of history the bright and dark lines have had their changing alternations. They are changing now and the shifting lines are slowly shaping the destinies of nations, young and old. Rightly or wrongly, by fair means or foul, the older nations are pushing their conquests or colonies wherever the opportunity offers, to retain their grip on commerce, by securing new markets for their surplus products. Commercial necessity has replaced the old lust of empire, and is really the key to the avidity with which Europe is dividing Africa as hunters do their game, and is casting its eye over continents and oceans for commercial territory. In the western hemisphere the same impulse is making itself felt with more or less of the same reasons, and is at the bottom of much of the idle but significant talk of annexations, protectorates and other forms of grabbing real estate. Taking this, however, at what it is worth, and leaving the grave hazards it involves to take care of themselves, it is beyond a doubt or peradventure a sober and undeniable fact that the routes of commerce are shifting from the Atlantic to the Pacific. In that direction lies the future arena of the world's struggle for commercial supremacy. A glance at the growth of populations from the western slopes of the Rockies to the sunset rim of the sea lines, and from Alaska to the Mexican border, with what it signifies of enterprise and development, we see the massing of a commercial momentum that will dot the Pacific with its ships and overlap the fringes of Asia. The eddies of this movement will eventually spread beyond the Isthmus to the Horn, and history will run its iron pen over an opening chapter in the story of man. With Siberia intersected with Russian railways and its areas populated; with Japan a new and potent factor in the East and China waking out of its loug slumher, to say nothing of the future of Australasia, with its persistent and aggressive race, it needs no prophet to forecast the coming change in the map of commerce. The place of the United States in this recasting of history is settled by its geography. Some years ago we outlined this route of destiny, and we see it more elaborately and broadly defined in a recent issue of the *North American Review*, in which the facts noted in this article are succinctly stated. From a national point of view this outlook is more than encouraging, and, we make hold to say, our destiny in this matter can be best reached not by jingo, but by the merchant and manufacturer accepting the situation and not neglecting its opportunities. There is no need to force the tide when it runs in our favor."

Formation of Coal.

The formation of coal, according to Dr. Homer Green's cosmical theory, was due to the solar orh bringing forth, millions of years ago, when it was larger and hotter than to-day, a wonderfully luxuriant vegetation, including plants of strange kinds, mosses as large as forest trees, and ferns thirty feet in height, growiug up richly from the clayey soil and forming dense jungles in the vast marshes, the latter covering great areas of the earth's surface; these ferns, mosses, and the leaves, branches and trunks of trees in time falling and decaying where they grew, only to render the soil more fertile and the next growth more luxuriant. Year after year, century after century, this process of growth and decay going on, until the beds of vegetable matter thus deposited became of great thickness; the earth's body, however, still continued to shrink, in consequence of which her crust at times contracted and fell in, the land then sinking throughout vast areas, the beds of vegetable matter going down and the water sweeping again over the great marshes, sand and mud and gravel were laid down anew over the deposits, and the clayey soil from which the next rich growth would spring was spread out on the surface, this process being repeated again and again, as often, indeed, as seams of coal in any coal bed. In this way, according to Dr. Greene, the conditions for the formation of coal were made complete, atmospheric air being entirely excluded, while the vegetable beds underwent the processes of decomposition, so that in some beds of coal whole trees have been found, with roots, branches, leaves and seeds complete, and all converted into the same kind of coal as that by which they were surrounded.

Wood Pulp for Horseshoes.

A practical invention by a veterinary surgeon is now successfully applied at Berlin. He manufactures horseshoes of paper, impregnated with oil or turpentine, to make it waterproof. After being saturated, it is glued together in thin layers with a cement which does not become brittle when drying, and consists of a mixture of Venetian turpentine, powdered chalk, linseed oil and lacquer. These horseshoes are made in various thicknesses. The holes, admitting the nails by which the shoe is fastened to the hoof, are stamped through the paper when moist. It is then subjected to a very strong pressure under a hydraulic press, and, when dry, can be filed and planed to fit the hoof snugly. The inventor has also attempted to make these horseshoes of paper pulp, adding chalk, sand, turpentine and linseed oil in such quantities that the material is impermeable to moisture. This composition possesses the necessary elasticity and toughness for the purpose. It can be pressed in moulds and dried afterwards, or cut out of blocks of the mass and placed under strong pressure. The shoes made by pasting together paper sheets are preferable, as they are stronger than those made of the compressed material. These shoes can be fastened to the horse's hoof either by nails, as usual, or be cemented with glue consisting of gum of ammonia, one part, and gutta percha, two parts. The great advantage claimed by the inventor for the new shoe is the impossibility of the horse slipping on slippery roads.

The Secor System.

The immense amount of fuel which it is necessary for trans-Atlantic steamers to carry occupies so much space that not enough passengers and merchandise in addition can be carried to make the vessels self-supporting. This trouble is to be obviated by the Secor system, which, stated in its simplest form, consists in the use of several inclosed cylinders, into which are introduced a mixture of air and atomized fuel, which being automatically ignited, is discharged directly against the external water at the stern of the vessel. The instantaneous explosion of the gases drives the vessel forward in the water just as a rocket is elevated in the air. The explosions, under perfect control, are produced with perfect regularity and average 300 per minute. This invention, it is thought, will cause as great a commercial revolution as that which followed the original introduction of steam.

It is now believed, and with high probability of the truth of the theory, that the shooting stars which sometimes fall to the earth in a semi-molten condition are almost or wholly devoid of heat when they enter the atmosphere. They are set on fire hy friction against the air due to the rapidity of their motion. It is possible that the force of the earth's attraction solidifies such meteors from a gaseous condition in which they may exist in space.

The sun has about 228,000 times the mass of the earth, and the moon only one-eightieth of this mass.

Mechanical Progress.

Induced Draft for Steamships.

In order to get more steam for an engine from the same furnaces and boilers, the natural draft is often supplemented hy an extra one, artificially produced. This may be done in two ways: Air may he forced into the fires from below, or it may be sucked in hy creating a partial vacuum ahove. The former method is the most common on steamships; the latter is usually practiced with locomotives, in which the desired effect is produced hy the discharge of exhaust steam into the smokestack. "Induced" draft, however, after being tried on some small vessels, is about to be employed on one of the largest battleships in the British navy, the Magnificent, launched a few weeks ago, and having a displacement of 14,900 tons.

Where triple-expansion, condensing engines are used, there is no exhaust discharge; and a different means of securing the desired object must, therefore, be adopted. In the present instance, there will be rotary fans in the "uptake," after designs by W. A. Martin. This expert in mariue engineering declares that a forced draft tends to concentrate the heat of a furnace at special points. This is advantageous in an iron foundry, but not in a steam hoiler. "The initial effect of such draft," he says, "is under the body of the fuel, and the gases generated are driven on without any controlling influence, whereas with induced or exhaust draft the initial effect is on the top of the fuel, and the gascs evolved are under the control of the draft until they are passed through the funnel." More complete combustion of the gases, the prevention of deposits of ashes in the tubes, aud longer life for the boiler are among the advantages claimed for the latter plan.

Sweeping with Compressed Air.

One of the most notahle of the present century's small inventions is an air pump for cleaning purposes. A hose pipe charged with air under fifty pounds pressure to the square inch is turned upon the article or room to be cleaned. It is used in precisely the same way as the water and the hose for washing purposes. It is far more effective in its result than brooms, beaters or brushes, as it searches out and penetrates every crevice and cleft in woodwork. This device is at present applied to cleaning cars, but so perfect is its work that it is only a question of time when it will come into use for other purposes. Hotels and large buildings might be swept out and dusted in an incredihly short space of time. Carefully managed, this air pressure would rid the room of every particle of dust, clean furniture, carpets and the heavier articles of hric-a-brac and ornaments. It would do the work of a dozen people. It is now in order for some home missionary to invent some simple device that will work an air pump and current for household usc. Its introduction would revolutionize housekeeping and solve the heretofore hopeless problem of clean rooms, and will keep furniture, covers and carpets. It would he economical, as it would render less service necessary, and would save a large portion of the wear and tear of furnishing textiles. In houses where there is hydrant water it would not be at all difficult to attach an air-pumping apparatus to the kitchen or bathroom faucet and thus furnish power for every floor. Some years ago it was said that there would never he an invention that could sweep the dust, but at the present rate of things the prohlem is practically solved by this simple and easily used device.

There may be some truth in the argument made against the use of low-water alarms; that they encourage carelessness or neglect, and that their use enables owners to economize by employing incompetent help at lower wages. These arguments are not good against the fact that every mechanical as well as personal precaution should be taken to guard against accidents or injury of every kind. It is Chinese logic to say a good thing is not a good thing because its use is sometimes abused. Every argument presented against the low-water alarm can with equal or greater force be directed against the safety plug. With a low-water alarm in good working order there is precious little use for a safety plug, as the alarm will arouse even the most careless engineer to action hefore the water gets low enough to melt the safety piug or even injure the boiler.

A Headlight for Curves.

An ingenious machinist in the Dunsmuir railroad shops, says the Redding *Free Press*, has constructed a swinging headlight on engine 1769 that works automatically. In going around sharp curves, headlights on locomotives being made stationary throw the light straight ahead instead of throwing it so that it follows the track, where the light should be at all times; and it was this that started the gentleman to thinking how to remedy the defect. The contrivance which he has invented for making the light follow the track is very simple, and it is a wonder it was not thought of sooner. In the first place he has made the headlight to hang by two pivots, one on top, the framework that holds it being fastened to the smokestack and the hottom one to the boiler-head, and from the bottom of the headlight two chaius run to the ends of an extending arm and this arm is connected by a rod which ruus to the pilot wheels truck. As the pilot wheels strike a curve the outside wheel of course forges slightly ahead and this movement works the rod and chain just enough to move the headlight so the reflection is cast directly ahead on the track. It is said that it works very well and in the winter season will be a great benefit to engineers, for on mountain roads where generally there is but little straight track, boulders often fall, and if there be no light ahead a train will strike one hefore it can possibly be stopped.

It has been settled in the minds of several mechanics who have given the subject of belting their close attention, that a belt two inches wide and of single thickness, running on a pulley eight inches in diameter, represents about as near a perfect belt transmission as it is possihle to get with oak-tanned leather helting. This may seem rather a favorable conditiou for a belt of this dimension to be working under, hut as far as the pliability of the belt is concerned no one would object to the curvature of eight inches, and as for the width, one inch and a half might be considered quite narrow, and three inches in width somewhat wide. However, if this oak-tanned material will endure all this bending action while under a high speed, and drawu up taut enough to give a good account of itself when power is to he transmitted, then it must be expected that a pulley sixteen inches in diameter, when provided with a double thick belt of four inches wide, is giving equally as good satisfaction. Not only this, but the three-ply leather helt should, on the same basis, be employed whenever two shaft wheels are to he connected that are twenty-four inches in diameter, and for a perfect width six inches must he considered about the proper dimension. At this rate many of the large belts that are in use are much too wide, and altogether too thin, which, no doubt, could be improved by giving some attention to this comparison.

M. Moissan has recently succeeded in preparing pure titanium by means of the electric furnace. The metal proves to be the most refractory of any he has yet dealt with, being less fusible than pure chromium, tungsten, molybdenum, uranium or zinconium. It is an extremely hard metal, capable of scratching the diamond. It is, however, soluble in lead, copper and iron.

Electrical Progress.

What Electrical Engineers May Expect.

F. H. Ford puts forward in an electrical journal a strong disclaimer of tbe statement which has been made in a daily paper, that "for the average young man the field of electrical engineering offers more promise of success than law, authorship, the grocery business or knife-grinding." Mr. Ford says that serious harm is being done in the continual holding up of the profession of the electrical engineer as one offering almost unlimited possibilities in the matter of salaries and demand for men. The closing of many large works owing to financial trouble or patent litigation bas thrown a large number of men of both experience and ability on the market, and the supply of engineers is in excess of the demand. The struggle for place which bas naturally followed bas forced down wages so low that the average engineer cannot command a better salary than tbe head bookkeeper of a large wbolesale concern. The young man who cbooses electrical engineering as a professiou must be prepared to work hard and long, and for wages wbich would ordinarily be considered inadequate for the work done. If he loves engineering for its own sake, there is as good a field in the electrical as in any brauch of it, but the idea tbat there are positions witb large salaries attached waiting to be filled by him is a mistake. There are but few high salaried positions at best, and they are occupied by men who have large experience and solid influence witb the capitalists at tbe back of the company. The young electrical engineer will be obliged to spend at least six years in preparation before he can earn enougb to barely pay bis expenses, and nearly all this time he will be paying out money instead of earning it. The same time speut in preparation for either law or medicine would qualify him for beginning practice, wbile if it were devoted to business or journalism, it should give tangible and satisfactory results. The young engineer usually has to start business for himself with very limited capital, if any, and has to accept a subordinate position witb some compauy. Here his best ideas as well as his best work are given almost entirely for the benefit of his employer, and he bas to suffer for bis failures as much as if be were working for bimself. Mr. Ford maintaius that the demand in electricity at tbe present time is not for educated electricians, but for educated capitalists wbo can understand that in the long run it will pay them far better to secure the services of capable officers who know why things should be doue, and who will look after economy in the output, than to hire cheap and irresponsible men wbo waste more than the salary of a good man in iuefficient methods of working. Mr. Ford thinks it is only wben capital has beeu so educated tbat the relation between work done and pay received by the electrical engineer will compare favorably witb that of the lawyer, the doctor, the writer and the merchant.

Signaling Through Space.

Iu further confirmation of the successful experiments concluded last year in England in transmitting telegraphic messages over long distances without wires, an accouut has been received from Scotland of the maintenance of telegraphic communication by means of the same system between the island of Mull and the mainland. The islanders were decidedly put to a shift. The six-mile cable which usually kept them iu touch with the other world had broken down, and they were uucertain as to how loug the interruption to communication would last. A local electrician, who had heard of Mr. Preece's plan, saw no reasou why it should not operate at Obau, just as well as anywhere elsc, and lost no time in running a gutta-percha insulated wire, one and one-half miles long, along the ground from Morvern, fifteeu miles from Oban, and signaling through that, while on the island of Mull the ordinary overhead circuit connecting two distant villages was made use of. The distance intervening between the two parallel circuits was about three and one-half miles. A vibrator was used as a transmitter, and a telephone as a receiver, and the usual telegraphic traffic was carried on until the cable was repaired. An account not so well authenticated comes from India of the completion by Professor J. C. Bose, of the Calcutta Presidency College, of some instruments by which extraordinary results are said to have been obtained. Certain phenomena have been reproduced without any connection between the transmitting and receiving stations. Siguals in the form of light and sound have been passed along the ether, without any other apparent means of transmission, and even solid walls have not interposed any obstacle to the passage of these signals.

Buda-Pesth's Underground Road.

A new double-track electric road in Buda-Pesth, the capital of Hungary, is being constructed under peculiar difficulties. In the first place, as the avenue through which it runs is handsome and fashionable, it was deemed best to put tbe road uuderground. But tbe existing sewers, to say nothing of gas pipes and water-mains, are located in the center of the street, at too great a depth to make it advisable to go under them, but bigh enough to leave only about nine feet of space between tbem and the surface of the street. Economical and otber considerations finally led the projectors to adopt a route above the sewers. In order to gain all the room possible in a vertical direction, tberefore, the upper surface of the sewers—whicb are circular—is shaved off here and there and replaced with a flatter iron cover, suitably stiffened, and the street level has also been raised a trifle. So thin is tbe arched tunnel roof tbat at its center a row of posts is needed to sustain it. It is thus practicable to get nine feet from the top of the rails to the under side of the overhead iron beams running lengthwise and buttressing the arch. A total widtb of 19 feet 8¼ incbes is secured. Sides, top and bottom are made of coucrete, but tbere are also irou cross-beams in tbe roof. What is called "asphalt felt" is introduced into the top and bottom to exclude water.

The current to operate the road is supplied by overhead wires, of which there are two for each track. The return is effected by a continuous copper conductor, and not by the rail. The tops of the cars come within four inches of the roof of tbe tunnel. Of course, the cars are bung very low. It is intended to operate them in trains instead of singly, but not to have one car communicate witb anotber. There is a block system wbich prevents a following train coming within a mile and a quarter of the one ahead of it. The current is switched off automatically if cars euter a block before they are entitled to. Again, at the end of the line the current is shut off automatically from the train. The line is to be ouly two miles long when completed, and it is now nearly half built.

THE subject of phosphorescent lighting—one that will afford illumination direct without the wasteful accompaniment of heat, and which will approach in efficiency that of the glow-worm—has recently received an added interest by the success of the experiments made iu this direction by D. McFarlau Moore. The line which Mr. Moore has marked out for himself contemplates the introductiou of phosphorescing glow lamps ou continuous or alternating current circuits of ordinary potential, with the addition of but the simplest auxiliary apparatus.

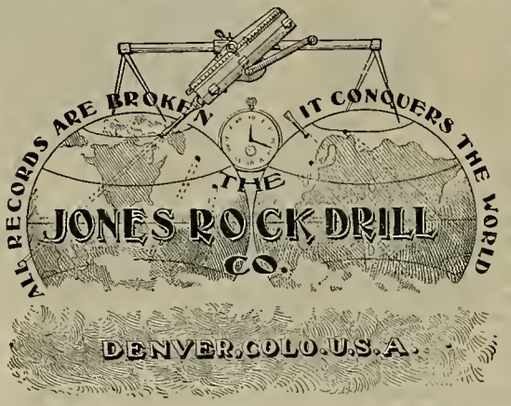
THESE five years have indeed done wonders in the domain of street railroading in this country, and have even set our transatlantic friends to work following our example, says Joseph Weltzer in *Scribner's* for May. To give some idea of tbe extent to which electricity bas displaced the horse, and, on the other haud, been instrumental in creating new roads, we need only cite the fact that at the present time there are over 850 electric railways in the United States, operating over 9000 miles of track and 23,000 cars, and representing a capital investment of over $400,000,000. Wbat stupendous figures wben we consider that in 1887 tbe number of such roads amounted to only thirteen, with scarcely 100 cars.

AMONG the securities enumerated in the assets in tbe report of the General Electric Co. for the year ending Jan. 31, '95, appear the following stocks: Los Angeles Edison Electric Co., $40,000; Portland, Or., General Electric Co., $527,800; Tacoma, Wash., Railway and Motor Co., $45,000; bonds: Los Angeles Cons. Electric R'y, $41,440; Portland G. E. Co., $67,000; Seattle Power and Railway Co., $21,000; Sacramento E. P. and L. Co., $10,000; San Francisco and San Mateo R'y Co., $15,000; Tacoma R'y aud Motor Co., $200,000; par value.

THE next convention of the National Electric Light Association will be held in New York City next May.

OUR esteemed contem., the *Electric Review*, is viewed as a humorous journal in the Soutb.

THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

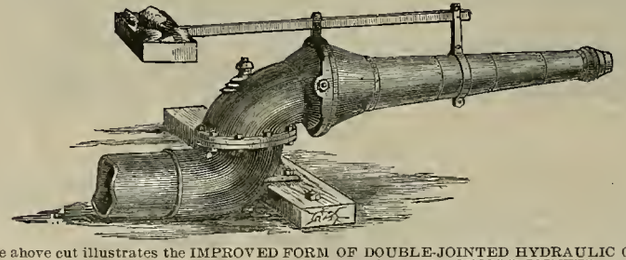
IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.

PLACER
Amalgamators, : Dredgers, : Shovels.

Complete "Lancaster" Gravity Gold Amalgamating, Hoisting and Dredging plants furnished for treating large quantities of low grade placer ground and pulverized free milling quartz at small cost with minimum supply of a water. **Highest possible Gold yield insured.**
The "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways are of the most improved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required. **Crushing, Pulverizing, Concentrating, Screening, Pile Driving and other machinery also built.** Investigation and correspondence solicited.

JAMES H. LANCASTER, Patentee, 39 Cortlandt St., NEW YORK.

Ball Bearings.

Commenting on the growing introduction of ball bearings, which, as may be remembered, first found practical use in diminishing the friction of bicycles, Dr. Coleman Sellers, in a recently delivered lecture, pointed out that one of the most notable examples of the use of the balls is to diminish the friction of the collar that sustains the hook of a large crane. Without the balls the difference between the friction of rest and the friction of motion is so great that men are often seriously hurt by endeavoring to turn a load suspended upon the crane hook, which requires a great deal of exertion to start it, and when it does move, goes farther than is intended, often leading to serious accidents. By making the crane hooks with flat washers, between which numerous small balls are placed, resting on hardened surfaces, there seems to be no difference between the friction of rest and the friction of motion, and hooks heavily loaded are turned with remarkable ease, so that the use of balls, distributed over plain surfaces, is quite common, there being no basket or grooves to separate the balls, which latter are allowed to move at their own will in whatever direction they are inclined to go. There is very little literature on the subject, and the theory of ball bearings has not been worked out and published. It may be interesting, however, to know that some experiments have been going on for some time past in reference to the size of the balls best suited to the different purposes. In the case of hooks for cranes carrying about fifty tons, between 250 and 300 balls, each of three-eighths inch diameter, are scattered between the flat plates, with the idea that the more points of contact the longer the belts will last; but some experiments are now being tried with balls of different sizes, and motion kept up under loads to determine their durability, with a leaning in favor of larger balls and fewer of them.

Too Much Tongue.

Where employment is given to more than one person, the bane of success is the talking man. One who has always something to say takes his own time and the time of others to hear his "too much tongue." Those employed may not stop work altogether to hear what is said, but they will lessen their efforts, and their minds will be diverted from their labor and less will be done. But the talking man usually succeeds in getting others to stop work for a short time to hear him, and if he is allowed to talk without hinderance he will consume a great deal of time.

Some of these "too much tongue" have a gift of almost continuous "gab." They will give the impression to others that they are keeping step with others and talk at the same time, but there is a lack of dispatch in their efforts, and there will be this same lack with the men who listen to them.

One of two things should be done by the employer. Stop the "too much tongue" by a kndly request, and if the request is not heeded, then discharge the fellow who wags it to the injury of the business. The party may be clever, good hearted and well meaning, but these good qualities will not compensate the employer for the waste of time.

Decision Against the Cowles Electric Company.

An opinion has been handed down by United States Circuit Judge Taft, of Cleveland, O., deciding a famous patent case which has been in court for a number of years. The suit was brought by Francis Lowery, executor of the estate of Grosvenor P. Lowery against the Cowles Electric Smelting and Aluminum Company and Alanson T. Osborn. The defendants claimed they had the right of two patents by assignment from Charles S. Bradley, for a process of separating metals, particularly aluminum, from their ores, by the use of an electric current, both to fuse and decompose the ores. They claimed they came into possession of the patents by virtue of a sale to Alanson T. Osborn, who was said to have assigned the right to the Cowles Electric Smelting and Aluminum Company. The plaintiffs, on the other hand, claimed that Bradley sold and assigned the patent right to them, and that they held letters patent at the department of patents in Washington. The Cowles people also held letters patent, and the suit was to determine which party was guilty of infringement.

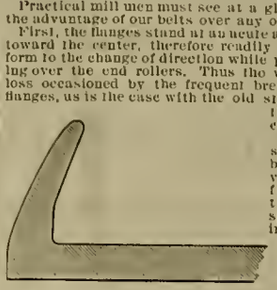
Judge Taft, in a voluminous opinion covering over fifty pages of type-written matter, held that the defendants had infringed and were not entitled to letters of patent. He granted the plaintiffs a perpetual injunction restraining the defendants from using the patent rights, and ordered the letters of pateut held by the Cowles company canceled and declared void.

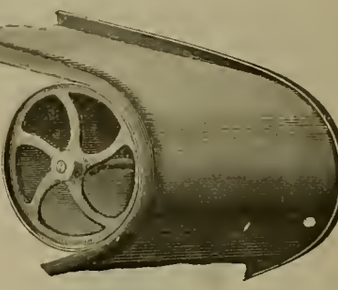
THERE is considerable excitement among Canadian miners over the discovery of phenomenal deposits of chromic or chrome iron in Coleraine. In one case it is only necessary to blast it from the side of a mountain, and four or five blasts suffice to furnish 100 tons. All thus far shipped out of Canada has been taken by the Carnegie Steel Company of Pittsburg. The ore averages for the most part over 50 per cent. of metal, costs little or nothing to mine, is found close to a line of railway, and is worth $25 to $35 per ton.

THE thumb, according to professional palmists, is an unerring index of the mind. If a person is trying to deceive you, he will invariably draw his thumb in towards the palm. On the other hand, if he is telling the truth, the thumb will be relaxed and point away from the palm.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.





Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome. Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty rifles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

H. G. BLASDEL, JR., Manager,

419 California Street, Haywards Building..... .....San Francisco.

GATES ROCK AND ORE BREAKER

OVER 3000 IN USE THROUGHOUT THE WORLD

PRODUCES A MORE PERFECT CUBIFORM MATERIAL AND A GREATER QUANTITY IN A GIVEN TIME PER HORSE POWER USED THAN ANY OTHER CRUSHER ON EARTH.

CAPACITIES UP TO 150 TONS PER HOUR. NINE DIFFERENT SIZES.

WE HAVE BUILT THE LARGEST STONE CRUSHING PLANTS IN EXISTENCE

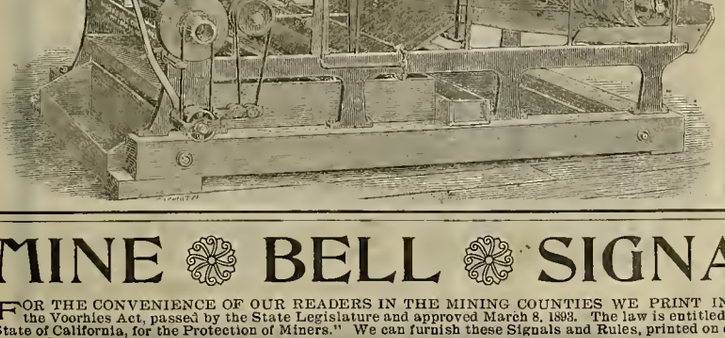
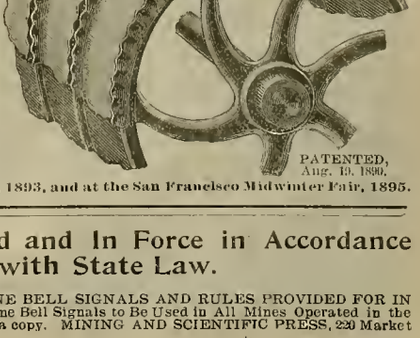
THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. Price $575 f. o. b. Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The Improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allowed to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect; Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury, Manufacturer, 141 to 143 First St. San Francisco, Cal.





PATENTED, Aug. 19, 1890.

This Concentrator took the 1st prize at the San Francisco Mechanics' Institute in 1890, 1891 and 1892, and at the California State Fair in 1892; it took the 1st prize at the World's Columbian Exposition, 1893, and at the San Francisco Midwinter Fair, 1895.

MINE BELL SIGNALS.

Adopted, Used and In Force in Accordance with State Law.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

Legal Decisions on Mining Questions.

Condensed by *The Colliery Engineer and Metal Miner.*

Placer Mining Rights.—One having a placer mining right, which can only be acquired on public land, can maintain suit to quiet title, if at all, only as to his limited interest.

Carter v. Thompson (U. S. Cir. Ct. Dist. Montana) 65 Federal Reporter, 329.

Placer Patent—Exclusion of Quartz Lode.—A lode or vein, to come with the Revised Statutes of the U. S., Sec. 2333, exempting it from the grant of a placer patent if its existence was known at the time of the application for such patent must be of such extent as to render the land more valuable, and of such value as to justify exploitation and development.

Brownfield v. Bier (Supreme Ct. Montana) 39 Pac. Rep. 461.

Deceit in Sale of Mining Stock.—The measure of damages on a sale of mining stock, voidable on account of fraudulent representations, is the difference between the real value of the stock at the time of sale and what the value would have been had the representations been true.

In an action to recover damages under such circumstances, the market value of the stock at or about the time of the sale is evidence on the question of its real value.

Representations by a vendor of mining stock that the purchaser could not lose on the investment, and that the mines would pay dividends in the near future, being a mere expression of opinion, or a promise of a future condition of things, will not form a ground of recovery by the purchaser on the ground of false representations.

Warner v. Benjamin (Supreme Ct. Wis.) 62 N. W. Rep. 179.

Action Against Mine Owner for Death by Wrongful Act.—The Court of Appeals of Colorado receutly decided the following points, in an action brought by a party for damages caused by the death of his son while working in a mine:

(1.) A parent may recover for the death of a child, although the latter never contributed to the parent's support.

(2.) In an action by a father to recover damages for the death of his son, evidence of an arrangement between the two, for a loan by the son to the father, is admissible on the question of damages.

(3.) A miner working in a shaft upon a high column of dirt, supported above the bottom of the shaft by a sufficient bulkhead, does not assume the risk of the additional danger caused by the removal of the bulkhead without his knowledge.

(4.) Where a miner worked in a shaft upon a high column of dirt, supported by a strong bulkhead, which was removed without his knowledge, he is not guilty of contributory negligence.

(5.) When the evidence as to the place where such party worked is sufficient to show whether it was safe, it is not error for the court to charge the jury that the mine-owner was bound to provide a reasonably safe place for him to work in, without defining what a "safe" place was.

Molly Gibson Con. Min. & Mill'g Co. v. Sbarp, 38 Pac. Rep. 850.

Appropriation of Streams on Public Land for Mining Purposes.—The Supreme Court of Washington holds that the Act of Congress, July 26, 1866, did not create the right to use by prior appropriation of streams on public land for mining and irrigating purposes, but simply recognized such right which had grown up through the acquiescence of the government and the universal custom of the locality.

Isaacs v. Barber, 38 Pacific Reporter, 871.

Interpretation of Contract of Sale.—Where a contract for the sale of coal during a period of five years provides that "settlements for said coal shall be made upon the 15th day of each month for all coal delivered before the 1st day of such month," and the buyers pay according to the terms of such contract, but under protest, because of the alleged inferior quality of the coal, the payments are voluntary, and cannot be recovered.

The court said: We can only understand this to mean that the amounts owing for coal were to be fixed, determined, adjusted, settled, at the middle of the month. We cannot hold that the parties having used such language meant really its opposite; that is, that although these monthly settlements were actually made, and the amounts paid, those preceding deliveries still remained open, subject to any kind of controversy which either party might choose to set up subsequently, throwing the whole subject of deliveries, which would necessarily include the amount and quality of the coal delivered, the prices to be paid, and all matters affecting those questions.

Armstrong v. Latimer (Supreme Ct. Penna.) 30 At. Rep. 990.

Failure to Enjoin Blasting is Not Contributory Negligence.—Where a contractor employed by a party to do blasting near another's house proceeded with the work in so careless a manner that such house was injured, the failure of the owner of the house to enjoiu the continuance of the work was not contributory negligence.

Berg v. Parsons (Supreme Ct. 1st. Dept.) 31 N. Y. S. Rep. 1091.

Action to Forfeit Mining Lease.—A mining lease which provides that it shall be void if "the enterprise shall be abandoned 12 months" is avoided by failure of lessee to commence mining operations within 12 months after the lease commences.

The fact that the lessee is unable to work the lands for lack of railroad facilities, and, that having leased other lands in the vicinity, he is approaching the lands in question as fast as he can, is immaterial.

An action by a lessor alleging his title to the land, and the execution of the lease to the party sued, which under its provisions has become void, and praying that the lease be declared void, will be treated as an action to quiet title.

In this case it was contended by the lessee that "the enterprise could not be abandoned unless it had been begun, and that it continued to subsist for the entire term, though not a single thing was done under it. The court said: We think it was clearly contemplated by the parties that a mining and quarrying enterprise was entered upon by the execution and acceptance of the lease, and if nothing more was done within 12 months after its execution, it would be an abandonment of the enterprise for 12 mouths; and therefore the lessor had the right to have the incumbrance on the title removed.

Woodward v. Mitchell (Supreme Ct. Ind.) 39 N. E. 437.

Gold in Iron Ore.

Samples of the Dexter mine ore in the Lake Superior region, taken from the stock pile were assayed recently by E. F. Bradt, chemist for the Lake Angeline mine, and were found to contain gold. The result of the assay was not a surprise to the management of the mine, as those interested in the property have known for some time past that the ore contained more or less gold. The samples were not taken from any particular part of the stock pile with a view to getting the best possible results, but were picked from different parts of the pile. According to the assay the ore contains gold at the rate of about $3.75 per ton.

The management feels greatly encouraged over the result, and intends to devise some means of treating the ore for the gold it contains. There are about 3,000 tons of ore in stock, and more is being added to the pile daily. The ore is a rich manganese and is always in demand. The mine is only a short distance from the Michigan and other gold properties in that vicinity.

In 1884 aluminum sold at $16 per pound. To-day the price is sixty cents per pound, in small lots, with reductions for larger quantities. It is used for almost everything, from steamboats to thimbles.

IT IS NOT WHAT

YOU PAY

FOR ADVERTISING,

BUT WHAT IT

PAYS YOU!

THERE ARE TWO VALUES to a purchase—what it costs and what it is worth.

Cork costs a few cents a pound, but if you are drowning half a mile from shore its value would be not what you pay for the cork, but what the cork pays you.

YOU ARE NOT DROWNING,

But you are struggling—struggling for business. The life-preserver in which you should place your dependence is *Advertising*. The value of that advertising is not what you do for it in the way of price, but what it does for you. It makes little difference what it costs within reasonable bounds. But it makes a great deal of difference what it is producing you every week.

IS IT NOT SO?

A series of advertisements for three or six months is not a large speculation, even at its worst; and it may be the means of putting

MANY THOUSAND DOLLARS

Into your pocket.

The *MINING AND SCIENTIFIC PRESS* covers the field it represents in the west half of America. It is read by the very men from whom you expect business. It is business for you to ask business of those men. They want what they see advertised in these columns, and have the money to pay for it. Subscribers who can't pay for a paper are not likely to have money to buy what is advertised in that paper, but the thousands of intelligent men who weekly read the *MINING AND SCIENTIFIC PRESS* in every mining town, superintendent's office, and purchasing department in this State, Oregon, Washington, British Columbia, New Mexico, Colorado, Montana, Utah, Idaho and Arizona are buyers of merchandise that you have to sell.

There is renewed activity in the mining world. It results in large additions of new subscribers to our already extensive lists, which in quality and quantity are not exceeded by any similar publication. The first thing a buyer or prospective purchaser of mines or mining machinery or apparatus of any kind does is to get this paper, and when read it is always put by for future reference.

"The most economical advertising is that which brings the most business for the money invested."

Our advice is cheaper than our advertising rates, but if the subject interests you write for particulars, for facts and figures that will demonstrate the truth of what is here asserted. We make no claim that cannot be verified. An advertisement in this paper is not a doubtful experiment. It is an investment, satisfactory to the advertiser.

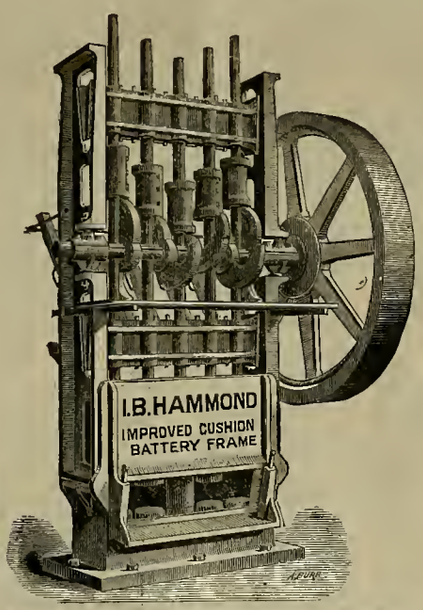
MANUFACTURERS OF

Stamp Mills, Ore Feeders

DETACHABLE BUCKET WIRE-ROPE TRAMWAYS,

Roller Grinding Pans, Desulphurizing Furnaces, Etc.



Improved Self-Contained Cushion-Frame Five-Stamp Mill.

The Improved, Iron-Frame, Self-Contained, Cushion-Frame, Five-Stamp Mill Saves Bills for Heavy Timbers, Millwright and Mechanics' Labor, and a Large Amount of Space. The Term "Self-Contained" Means a Great Deal to the Mine Owner, and Can Be Readily Recognized and Appreciated in Making an Estimate For an Ordinary Five-Stamp Plant, When the Comparative Cost is Considered Over a Wood-Frame Mill.

FIRST: There is Saved by the Use of This Mill a Large Bill for Heavy Timbers, in Many Instances Obtained at Great Expense and Loss Of Time.

SECOND: The Saving in Mill-Wright and Mechanics' Labor in Framing and Erecting.

THIRD: The Large Amount of Space Saved.

Sole Manufacturers of

Kendall's Patent Quartz Mills.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at **Greatly Reduced Prices.** Having made and sold these mills for the past 14 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach or all a light, cheap and durable mill that will do all that is claimed for it and give entire satisfaction.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators.

BY P. M. RANDALL.

This work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

TABLE OF CONTENTS.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulæ and Rules; Flow of Water Through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels, Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, $3.00, postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

A 1200-FOOT DRIFT.—A drift 1200 feet long is to be run on the 1000-foot level of the South Eureka mine, at $3.48 per foot.

GWIN MINE.—*Republican:* The Gwin mine shaft is down 700 feet. It is the intention to go 25 feet deeper, and then cut a station and start a crosscut to cut the ledge to ascertain its character. There are twenty-one men all told on the payroll. The drifting will be by contract. At this depth a tank is to be put in capable of holding 200,000 gallons of water. This will catch most of the surface water, and greatly facilitate the drainage of the works.

Butte.

FORBESTAWN DISTRICT.

THE STOW TUNNEL.—*Mercury:* The Stow mine and mill are upon a slope of the mountain two miles from the South Fork of the Feather river, the principal workings are through a shaft 360 feet deep with numerous levels and stopes. The descent from the mouth of this shaft to the river is very rapid, probably a thousand feet to the mile. Mr. Stow conceived the idea that by going down the mountain side and running in a tunnel the ledge would be tapped at a great depth, the mine thoroughly drained and the ore could all be run out through the tunnel, thus avoiding the the cost of the hoisting and pumping, and it is the ultimate intention to move the mill to the mouth of this tunnel. Calculations show that from the mouth to where it is expected the ledge will be encountered, is a distance of about 1200 feet. The face of the tunnel will then he 500 feet below the present lowest depth, vertically, or about 1100 feet on the pitch of ledge. It will be readily seen what an enormous amount of ore can be stoped down at comparatively slight expense.

The tunnel is all the way through solid greenstone, and is about eight feet square. Last month 102 feet were run. It is now in 600 feet or about half way.

Calaveras.

GREEN MOUNTAIN MINE.—The new eight-stamp mill at the Green Mountain mine in Chili gulch is finished. The upper tunnel is in 500 feet, the lower one 300 feet. The upper tunnel will he used as a flume.

GENERAL NOTES.—*Echo:* The Lockwood mine has been shut down duriug the last two mouths, but the present bond owners, Messrs. Rosenthal and others, of San Francisco, have orgauized and intend opening up again in a few days.

Joel Rowe, owuer of the Henry, Billy Williams and Skull Flat mines, has bonded them for $50,000.

LONE STAR.—Mr. Hurley, one of the principal owners of the Lone Star miue, was in Angels Camp last week arranging for the opening up of this mine, which will be worked on an extensive scale and bring joy to the hearts of the people of West Point.

BLAZING STAR.—Mr. Forester, the owner of this miue, is in San Francisco arranging for further improvements. It is his intention to build chlorination works which will be of great service to him and others in that vicinity in working the coneentrates, as the ore is mostly high grade. This property, with the Matrimony, Water Lily, Wide West, Smith and Bartola, have been bonded for $300,000, says the *Echo*.

BOSTON MINE.—The *Echo* hears that the owner of the Boston mine has refused $350,000 for it. Col. Robiuson, the superintendent, expects to find it another Utica.

El Dorado.

IN THE GARDEN VALLEY DISTRICT.—Work is being done on Collins' mine; prospects good. Rosecrans mine is still tied up in litigation, as is also the Lone Jack. The Emma mine is heing worked as usual. The Gardeu Valley miue will he operated as soon as the dry season comes. It is believed the Esperanza mine will have a mill erected this summer. The mine is well opened; shaft 200 feet in depth; 500 feet of levels and erosscuts.

Kern.

THE TALC MINE.—The Talc mine is located twenty-six miles from Delano and thirty-five from Bakersfield, in the White River country, in granite formation, the claim being 1500x600 feet.

The gouge is four feet in width, the pay streak six inches to two feet. The vein crops tbe whole length of the claim, and there is pay ore at all points.

The workings consist of a double compartment shaft, four feet by eight at the mouth of tunnel No. 1, a depth of sixty feet. In the face of the drift at the fifty-foot level pay ore is exposed. Tunnel No. 1 is in 600 feet—all the way on the vein and in pay ore—the longest continuous ore chute in the district.

Forty feet from the mouth of the tunnel No. 1 a winze has been sunk to a depth of 80 feet, exposing a ledge of varying width all the way down, the vein in the bottom being stronger and better than at the top. Tbis tunnel taps the vein 150 feet below the apex of the hill back of the mine.

The mouth of tunnel No. 2 is fifty feet farther up the hill and is driven in 400 feet, and is connected by air shaft with tunnel No. 1, securing perfect ventilation of all the workings.

A 3½-foot Huntington mill, of eight tons capacity every twenty-four hours, is kept running day and night nearly all the time.

THE BALN MOUNTAIN MINE.—The following is from the *Californian*: A. P. Ellis of Glenville has been working at Bald Mountain mine, White River district. Walter Williams and William James leased 190 feet of the mine and entered an old shaft and drifted to the ledge. They found a vein of rich iron ore bearing gold estimated to carry $500 to $2,000 per ton. They have taken four tons of ore by working ten feet in length and eight feet in height. They know that the vein goes at least four feet deeper, and it is about eight inches wide in the bottom. You can see the gold everywhere by candle-light in this vein. They have fifty feet above them to stope out. It beats everything ever seen in the mine, or ever heard from Indian stories. Mr. Ellis offered to take one hundred and fifty pounds of the rock for a month's work and was refused. They think they can easily get a carload of this ore within the next ten days. The mine is owned by an English company and superintended by Nelson Halleck. In the main lead they have a vein two and a half feet thick that yields forty dollars per ton. The same company has a force of eight men taking out good ore from the Eclipse mine.

Los Angeles.

NEW YORK CAPITALISTS AFRAID.—Los Angeles *Times:* The *Times* is in receipt of a letter received by a gentleman in Los Angeles from a correspondent in New York in reference to mining properties in Califoruia and Arizona. The writer states that at the present time New York is, without exception, the poorest city in the United States to float any enterprise—mining or commercial. Capitalists, he says, have lost all enterprise, all that they think of being to loan money on call on securities dealt in on the Stock Exchange. He adds that this state of affairs bas been produced hy the demonetization of silver, which makes gold perform a double function, with the result of increasing the purchasiug power of gold as the consequence, the lowering of prices of manufactured goods, as well as agricultural products. The writer, in conclusion, says that such a condition of affairs has unsettled trade and produced a want of confidence which, in turn, has caused capitalists to shut down on new enterprises, and that for all this there is but one remedy, the remonetization of silver relieving gold of its present double duty.

Nevada.

WASHINGTON DISTRICT.—*Transcript:* At the Washington mine nothiug is doing except keeping the mine free from water. The same thing has been going on for four years with no signs of a change.

At the German mine, nothing can be done in regard to starting up the mine till after the third of July. Then if the old company fails to redeem the mortgage bond amounting to eleven thousand and some odd dollars, new parties may step in and start up the mine again. At the Blue Jay mine, owned by Baugh and Bonney, four men are steadily employed. Their ledge is large, rich and well defined, and their little five-stamp mill is kept running on good rock both night and day. This mine has proven the richest in this district so far as it has been developed. The Last Chance mine, at the head of Diamond Creek, has recently been sold for a good round sum to Sacramento parties. It was a part of the Yuba mine property at Maybert. There was some talk not a very long time ago about the Yuba mine at Maybert being sold but there was no truth in the report.

THE ORO FINO.—The "Curry ledge," now known as the Oro Fino, owned by Messrs. Caldwell and Curry, is to be systematically worked this summer. A ten-stamp mill is being put up.

THE MORNING STAR.—The shaft at the Morning Star mine, Gold Flat, is being enlarged, with two compartments. The machinery will run by water power. A pipe line 4000 feet from the South Yuba Water Company's reservoir on the hill will give sufficient pressure.

Plumas.

QUINCY MINING AND WATER CO.—Warm weather has furnished water, used to good purpose against a large bank of gravel which presents every indication of yielding excellent returns. The impounding works are a complete success in their retention of the debris discharged from the sluices.

Below the water storage reservoir, and along the ridge sloping down from Spanish Peak, is a vast area of mining ground containing ancient river channels and deposits of gold-bearing gravel broken from them. This slope extends down to a point north of Quincy. Already many hundred thousands have been extracted in a small way, from the territory named, just sufficient to show what can be done by a proper expenditure of capital for development purposes.
